Virgin'ia, Univer'sity of, was chartered in 1819 with a constitution prepared by Thomas Jefferson. It was opened in 1824, and had then among its professors George Long and Thomas Hewitt Key, afterwards well known in connection with the University of London. It is divided into 16 different schools, each under a separate professor, and it has no imperative curriculum. It is directly under State patronage, and receives annually a grant of $30,000. It has 11 competitive scholarships open to natives of any State, besides 40 agricultural scholarships, founded in 1869. Its library contains 36,000 vols. The number of professors in 1876-77 was 17, and of students 330.

Virgin'ian Cree'per. See VITACEÆ.

Virgin'ian Quail (*Ortyx Virginiana*), a species of Rasorial birds belonging to the family *Odontophorinæ*, and nearly allied to that of the partridges or *Perdicidæ*. In the genus *Ortyx* the edges of the beak are sinuous or wavy, and the wings have the third to the sixth quills longest. The outer toe is united to the inner at the base. The V. Q. is also named the V. 'Colin.' It attains a length of 8 or 10 inches, and is of a reddish-brown hue, mingled with grey and black above, and yellowish white below. The head and breast are reddish brown and the chin pure white. The voice is clear, and the note resembles the words 'bob-white'—a name often familiarly given to the bird. The V. Q. feeds mostly on grains and inhabits open grounds, but in winter it approaches the habitations of man. The eggs may number as many as twenty-four. The bird is trapped in great numbers in winter. Its flesh is highly esteemed.

Virgin's Bower. See CLEMATIS.

Virgula'ria, or **Sea-Rod**, a genus of *Cœlenterate* animals belonging to the order *Alcyonaria* and family *Pennatulidæ*. The V. are common round the British coasts. Each of these organisms consists of a colony of polypes, having a sclerobasic or axial coral. The tentacles are pinnate. *V. mirabilis* is a familiar species.

Viria'thus, the shepherd-leader of the Lusitanians, or ancient inhabitants of Portugal, in their struggle for independence against the Romans, was one of the survivors of his countrymen's massacre by Sulpicius Galba (B.C. 150). Thenceforward he carried on in Lusitania and Southern Hispania a successful guerilla warfare against a succession of Roman proconsuls, winning two pitched battles, and in 141 entrapping the army of Quintus Fabius Servilianus in a mountain pass. Unconditional surrender was followed by alliance and a promise of independence; but within a twelvemonth Servilius Cæpio, the next proconsul, again took the field, and bribing some Lusitanian envoys, procured the assassination of V. (439), with whose death the conflict was virtually ended.

Vi'rus (Lat. 'a poisonous fluid') is a term used in medicine to designate the *materies morbi* of Zymotic Diseases (q. v.). It more specially designates those peculiar poisonous matters which can reproduce themselves under favouring conditions to an endless degree. The poison of the cobra is a specific V., which, when introduced into the human system, acts as a most virulent poison; but the poison is not multiplied within the human subject, and one person affected by the poison cannot communicate the disease to another. In like manner, morbid products from decaying vegetables under certain conditions of heat and moisture may possibly originate the V. of

malarial fever, but the V. is not propagated within the human organism, or, at all events, never in such a form as to render it capable of producing the same disease in others. By some the V. of the contagious or infectious diseases is supposed to be a *contagium vivum seu animatum*, the theory being that the V. consists of living beings or low organisms. Such views have been advocated by Kircher, Lancisi, Vallisneri, Reaumur, Linné, Henle, Roberts, and others; and although the theory of a *contagium vivum* is not as yet complete, the discussion of it is the most important which has ever engaged the attention of medical men. The most prominent characteristic of each specific V. is that it can reproduce itself within the human organism, and to an unlimited extent, each V. preserving its own specificness. Experience and observation tend to confirm the hypothesis that each specific disease breeds true, though, in the course of a thousand years, it is possible that changes within certain limits may take place, as is the case in animals and plants. The natural conclusion follows that diseases of this class do not originate spontaneously, but are propagated each from its own kind, though some contend that they do originate, even in our own day, spontaneously or autochthonously. Another remarkable peculiarity belonging to many, but not to all, diseases propagated by a specific V., is that a single attack of the disease successfully surmounted produces absolute or relative immunity for a certain length of time, or even for the remainder of life. See GERM THEORY OF DISEASE and ZYMOTIC DISEASES.

Viscon'ti (that is *Vice-comites*, or viscounts), a family famous in the history of Northern Italy, descended, according to their own account, from Desiderius, king of the Lombards. A certain Heribrand, or Eriprand, of the name is mentioned in 1037 at the siege of Milan; his son Otto became 'viscount' of the archbishopric of Milan about 1075; and a second Otto, grandson of the first, ascended the archiepiscopal throne in 1263. Archbishop Otto left the government of Milan to his nephew Matteo, who held the rank of imperial vicar of the city; but Matteo was excommunicated by Pope John XXII., whose claims on the archbishopric he had persistently resisted, and died about three months later, in 1322. Galeazzo, his son and successor, had a short and troubled reign, terminated by his death in 1329, and it was reserved for Azzo, Galeazzo's eldest son, to raise the reputation of the family higher than it had yet stood by his wise and merciful government of Milan, his successful wars, and his liberal patronage of the arts of peace. The grateful inhabitants to the number of 3000 put on mourning for his death, which took place August 1339. As Azzo died without children, his two uncles, Giovanni and Lucchino were now invested with the government —the former acting as bishop, and the latter as temporal sovereign. On the death of Lucchino (1349), who had been vicious and tyrannical, the bishop succeeded to his authority, and before he died in 1354 he had increased his dominion by the purchase of Bologna and the acceptance of the lordship of Genoa. Of the three nephews of Giovanni one died in 1355, and the V. possessions were divided between Barnabo and Galeazzo, of whom the former is mainly memorable for his contest with Pope Urban V., while the latter united the culture of a Mæcenas with the cruelty of a Dionysius, being equally famous as the patron of Petrarch and the deviser of a system of torture (Galeazzo's lent). On Galeazzo's death, his son Gian-Galeazzo began his remarkable career by getting rid of his uncle Barnabo and his sons. By a consummate policy, supported and carried out by the ablest diplomatists and warriors of the time, he gradually succeeded in extending his authority over the whole of Lombardy, and in making his influence felt not only throughout Italy, but in other parts of Europe. From the Emperor Wenceslaus he purchased the title of Duke of Milan in 1395, and the crown of Italy seemed almost within his grasp when he died, December 3, 1402. He had solidified his dominions into a state with a centralised administration, and, in the words of Professor Villari, deserves to rank as the first of modern as opposed to mediæval princes. To literati and artists he had been a bounteous patron, and two of the noblest buildings in Lombardy—the cathedral of Milan and the Certosa of Pavia—belong to his reign. Unfortunately his sons were unworthy of his fame. Giovanni Maria, who kept a pack of dogs for the purpose of tearing his personal enemies to pieces, was stabbed in 1412; and when Filippo Maria died in 1447 he left behind him the memory of little more than duping of men and waging of wars. He was succeeded by Francesco Sforza, his ablest soldier and subtlest enemy, who had married his daughter Bianca. See Lilla, *Familie Celebri Italiane*; Verri, *Storia di Milano*; and Villari, *Niccolò Macchiavelli and his Times* (Lond. 1878).

Viscon'ti, Ennio Quirino, a celebrated Italian archæologist, was born at Rome, November 1, 1751. A translation at the age of thirteen of the *Hecuba* of Euripides into Italian verse (Rome 1765) was a striking proof of the precocity of his scholarship. He was successively librarian in the Vatican (1771), Conservator of the Capitoline Museum (1784), and Minister of the Interior during the French period in Rome. In Paris, whither he fled in 1799, he was appointed Administrator of the Museum of Antiquities in the Louvre, and Professor of Archæology. He died February 7, 1818. His chief works are the continuation of *Museo Pio-Clementino* (Rome 1782-1807, 7 vols.), begun by his father, **Giambattista Antonio V.** (born 1712, died September 2, 1784), *Iconographie grecque* (Par. 1808, 3 vols.), and *Iconographie romaine* (Par. 1818-20, 3 vols.). Collections of his miscellaneous works were published at Milan (12 vols. 1818-22, and 3 vols. 1827-30). His brother, **Filippo Aureliano V.** (died 1831), was the author of *Museo Chiaramonti* (Rome 1808), in continuation of the *Museo Pio-Clementino*, and his son, **Louis Tullius Joachim V.** (born 1791—died December 1, 1853), is remembered as the designer of the tomb of Napoleon I. in *Les Invalides*, and of numerous public monuments and fountains throughout Paris. See Zannoni's *Elogio* of E. Q. V. in Florentine *Antologia*, No. xviii.

Vi'scount (Lat. *vice*, 'instead of,' and *comes*, 'count'), originally a designation of the sheriff of a county (an earl's vicegerent), was, in England, first bestowed upon John, Baron Beaumont, by Henry VI., in 1440, as an hereditary title, ranking fourth in the order of the British peerage. Viscounts, of whom there are now 67, received from James I. the privilege of wearing coronets, with a row of 12, 14, or 16 pearls, set on a circle of gold, while the mantle has two and a half ermine doublings.

Vis'cum. See MISTLETOE.

Vise (Old Eng. *vice*, *vys*; Fr. *vis*, 'a screw,' *Escalier à vis*, 'a winding stair'), a staircase winding round a perpendicular pillar called a *newel* (Nor. Fr. *nowel*). The steps are each formed of a single stone, and one end forms part of and is supported by the newel, while the other end is inserted into the wall.

Vish'ni-Volotchok', a town of Russia, government of Tver, on the Zna and the canal joining that river to the Tverza, 218 miles S.E. of St. Petersburg by rail. It is the central point of the V. system of canals, which includes 76 lakes and 106 larger and smaller rivers; and through the Tverza, an affluent of the Volga on the one hand, and the Msta, the Volchov and Lake Ladoga on the other, it connects the Caspian and the Baltic. The chief industry of V. is cotton-spinning. Pop. (1875) 17,400.

Vishnu' ('the encompasser or penetrator of the universe' according to Sanskrit commentators, from the root *vish*, 'to pervade'), the second god in the Hindu trinity, appears in the early Vedas as the manifestation of the Sun. In the later mythology, as represented by the Puranas, he becomes the supreme god, whose Avatars or incarnations (lit. descents) are necessary to restore order in the world. Of these Avatars 10 are generally enumerated, the last being yet to come. Some have evidently a cosmical explanation, but others may be thought to have a basis of historical fact. In the first five, V. appeared in the shape of various animals, the most popular representations being the fish, the tortoise, and the boar. His later Avatars were in the human form of the national heroes or demigods, Ram and Krishna, by which names he is commonly worshipped. Among his innumerable other titles may be mentioned Juggernauth, Narayan, and Parasuram. His wife is Sri or Lakshmi, the goddess of fortune. His adventures are described in the ancient epic of the Ramayana, and in the more modern poem of Jayadeva; and his worship, as opposed to that of his rival Siva, is inculcated in certain of the Puranas, chiefly the V. Purana, which has been translated with notes by Professor H. H. Wilson (Works, vol. vi. Lond. 1864). See Lassen's *Indische Alterthumskunde* (2d ed. Leip. 1866); Dr. Muir's *Original Sanskrit Texts*, vols. i. and iv. (Lond. 1858, 1863); and Monier Williams' *Hinduism* (Lond. 1877). Six principal sects of V.-

worshippers are enumerated at the present day. See also VAISHNAVS.

Vis'ible Speech, the system of expressing speech-sounds by written symbols, invented by Mr. Melville Bell during the years 1849–64. Its fundamental principle is, says its author, 'that all relations of sound are symbolised by relations of form, each organ and each mode of organic action having its appropriate symbol, and all sounds of the same nature produced at different parts of the mouth (such as *t* and *d*, *b* and *p*) being represented by a single symbol turned in a direction corresponding to the organic position.' The shapes of these symbols not being founded on any existing alphabet, the system here can only be illustrated, in the absence of the peculiar fount, by two that bear an accidental likeness to our current letters—O, symbolising that the throat is open, and C, that part of the mouth is contracted; and it is this creation of a novel type that, for reasons given under PHONETIC SPELLING, will probably always hinder the general adoption of the system. Among the advantages claimed for V. S. by Mr. Bell are its power of representing the exact sounds of foreign languages (even Zulu clicks), and the facilities offered by it towards teaching the illiterate and blind to read, and the deaf and dumb to speak. But though the first at least of these claims has been established by rigid tests, and is admitted by Mr. A. J. Ellis and other eminent phonologists, the system has not, as its inventor hoped, been taken up by Government, and so for want of oral demonstration, which only could make it popular, remains enshrined in his costly *V. S.: The Science of Universal Alphabetics* (Lond. 1867).

Vis'igoths. See GOTHS.

Vi'sion, in regard to the psychological and metaphysical questions to which it gives rise, is connected with the most abstruse questions in philosophy. These questions take their rise from an analysis of the testimony of consciousness on the subject, which proves that V. is to a great extent a *mental process*, and not (as the uneducated believe) a mere physical act. The theory has been ably elaborated by Berkeley, and has 'on the whole kept its ground as the acknowledged modern theory of V. amid the proverbial fluctuations of thought on such subjects.' It has been frequently quoted as 'the solitary example of a discovery in metaphysics.' Its main outlines are as follows. What we really see is only coloured points, and what we think we see we really infer from these. These coloured points, moreover, are presented to us in a plane, and therefore we cannot see distance—that is, we cannot see space. Space means 'room to move in.' We learn its existence by moving about, and when we say a thing is half-a-mile away, we mean that we would require to go through so much movement (with accompanying sensation) before we could reach it. Thus distance, magnitude, and relative situation between existing objects (all of which of course imply space of three dimensions), are all inferred, or (to use Berkeley's term) suggested by what we see, but are not themselves seen. Some of the signs that suggest distance are—A. Near distance. (1) Organic sensation in the eye; (2) degree of confusion in visible objects; (3) the organic sensation of straining. B. Far distance. (1) Number of intervening objects; (2) faintness of visual impression, &c. Were we without the power of motion, and did we open our eyes for the first time, we would only see coloured points; and then if we recovered the power of motion, we would gradually build up for ourselves that external world that we now know through V. As the things seen are the signs of what is not seen, so V. is a language by which (such is the ultimate form of Berkeley's philosophy) God speaks to us. The whole world, when properly understood, is the Divine language of its Creator. See Berkeley, *New Theory of V.*, together with supplementary dissertations and full quotations of authorities in the first volume of Fraser's edition (4 vols. Oxf. 1871). For the physics and physiology of V., see EYE; PERSPECTIVE; STEREOSCOPE; also COLOUR-BLINDNESS; HALLUCINATIONS; OPTICAL ILLUSIONS; and SQUINT or STRABISMUS.

Vis'on, a genus of *Carnivorous* quadrupeds included in the *Mustelidæ* or weasel family. Of this genus the Mink (*V. lutreola*) is the most familiar example. It inhabits N. Europe and N. America, attains a length of a foot and a half or rather less, and is of a brown colour, marked with white on the chin and jaws. The V. swims with great ease, the feet being slightly webbed. The fur is very valuable.

Vis'tula (Pol. *Wisla*; Ger. *Weichsel*), the largest river that flows into the Baltic, rises in Austrian Schlesien, on the N. slopes of the Bieskiden, and is formed by the union of the Black, the White, and the Little Vistulas (Biala, Molinka, and Czorna). It flows N. to the village of V., where it forms a waterfall 190 feet in height, then through a rocky valley to the town of Schwarzwasser, where it leaves the mountain-land. It next separates Prussian Schlesien from Austrian Schlesien and Galicia, and after receiving the Przemza, flows N.E., passing Cracow, and separating Galicia from Poland as far as Sandomir, where it receives the San, and turns N.N.W., then W., across the great plain of Poland, passing Warsaw, Nowo Georgiewsk, and Plock, and receiving the Pilica and Bug. Near Thorn it enters Prussia, and continues a N.W. course until it receives the Brahe below Bromberg, when it turns sharply N.N.E. At Montau, near Marienwerder, it divides into two branches, the smaller of which, called the Nogat, discharges into the Frische Haff, while the larger or western branch, after flowing 40 miles further, again divides at Fürstenwerder into two branches, the smaller or eastern falling into the Frische Haff, and the main branch turning W. and falling into the Baltic at Weichselmünde, 3 miles N. of Danzig. The total length of the V. is 694 miles.

Vita'ceæ, or **Ampelid'eæ**, is a small natural order of polypetalous dicotyledons, consisting of climbing plants with alternate simple or compound leaves; a small calyx; petals valvate in bud; stamens opposite the petals; fruit a berry with one or a few hard seeds. Besides the great genus *Vitis* (see VINE), which now includes the genera *Cissus* and *Ampelopsis*, the order comprises the small genus *Pterisanthes*, and the somewhat anomalous genus *Leea*. The Virginian Creeper (*Ampelopsis hederacea*), a rapid-growing creeper, native of the United States, is often planted to cover walls, to which it attaches by sucker-like discs terminating the tendrils. Its leaves turn red in autumn, when the plant presents a very striking appearance.

Vi'tal Statis'tics are statistics that relate to human life, such as the rate of births, deaths, and marriages, the increase of population, the average duration of life, and the health of the community. The compilation of such statistics is of great social importance. The sanitary reformer is guided as to the causes of disease in towns and districts, the physician is assisted to a knowledge of the effect of diseases upon individuals, and the ages at which they are most fatal, the actuary is enabled to make his calculations of risks dependent upon life, and the economist learns the laws of population and the lessons to be derived from them.

Complete registration of births, deaths, and marriages is necessary in order to obtain full data regarding the population of any country. In the United Kingdom very elaborate records of these events have been kept since the year 1837, but although every year shows a diminution in the number unrecorded, there are still considerable omissions in registration, particularly among the poor, owing to the neglect of clergymen, physicians, and other parties to give the required notice. The annual reports of the Registrar-General, however, are full of important information, and are the most valuable treasuries for the student of V. S. To the 39th Annual Report published in 1878 we are indebted for the following figures:—The increase of the population of this country since 1837 has averaged 192·873 souls, while 202·868 of a surplus have emigrated. While the average of births has been 1·039·987, the average of deaths has only amounted to 644·214. The natural increase of the population arising from the excess of births over deaths in England and Wales alone in the year 1876 was 377·653, while the loss to the population by excess of emigration over immigration was estimated at 38·065. In the period from 1837 to 1876 the economic value of the population has been increased by sanitary measures and judicious legislation. Municipalities have vied with each other in hygienic improvements resulting in a diminished rate of mortality among children, and from zymotic diseases. Thus in 1848–49 the cholera epidemic in England and Wales was fatal to 53,000 people, and the slighter epidemics of 1854 and 1866 show how this plague is under the control of science. The mean lifetime or average duration of life of an individual is, according to the English Life Table, compiled by Dr. Farr from the Government returns, 40·86 years. It is by

the Healthy Life Table compiled from the returns from healthy districts 49·0 years, or an increase of nearly one-fourth, which should be attainable in every well-organised State.

Marriages.—201,874 marriages were solemnised in England and Wales in 1876, being at the rate of 16·7 to every 1000 of the population, or ·1 less than the mean of the previous ten years, probably accounted for by depression in trade and a bad harvest. It is important for the solution of many social problems that the precise age at marriage of both parties should be in every case recorded, and there are still many shortcomings in this matter. The mean age of marriage of the ages ascertained in England in 1876 was 28 years for men, and 25·8 years for women, or dividing the marriages into first and subsequent marriages it was 25·7 years for bachelors, 24·4 years for spinsters, 43·1 years for widowers, and 39·5 years for widows. The mean age for men in the case of first marriage thus exceeded that for women by one year and $\frac{7}{10}$ths. There seems an increasing tendency to early marriage. In the period 1841–45, 4·38 per cent. of the males and 13·33 per cent. of the females who married were under age. In 1876 this percentage had increased to 8·25 for males and 21·99 for females. The marriage-rate in Scotland during 1876 was 15·1 per 1000 of the population. The figures for Ireland are incomplete and unreliable.

Ages at Marriage.—Actuaries have frequently questions submitted to them involving the risk of birth of issue to presently unmarried persons usually of good social position, to determine which statistics of ages at marriage are required. In Mr. Day's paper on 'Statistics of Marriage among Families of the Peerage,' published in No. 48 of the *Journal of the Institute of Actuaries*, the combined results of 3666 cases are published. The marriages of the aristocracy are fewer before thirty than those of the general population, about thirty they are equal, and for the remainder of life they are in excess. Mr. T. B. Sprague laid a paper before the Institute of Actuaries, 31st March 1879, on the 'Construction of a Combined Marriage and Mortality Table.' The probability of a peer marrying in a year is 0·01 at twenty, ·073 at twenty-five, ·074 at thirty, ·045 at forty, and ·011 at fifty. Of 100'000 peerage bachelors entering at fifteen there are 87·015 survivors at thirty, of whom 45·266 are unmarried, and 41·749 married, and at sixty there are 58·724 survivors, of whom 10·346 are unmarried and 48·378 married. According to the V. S. of the City of Philadelphia for 13 years, the probability of a female marrying before age twenty is 1 to 5 of all the probabilities she will ever marry, while at twenty-five two-thirds, and at thirty six-sevenths of the probabilities are lost. Statistics would seem to prove that married men as a rule are longer lived than bachelors; but this is misleading, as the general body of men are in good health at marriage, and a large proportion of men remain bachelors on account of physical weakness. Marriage, in fact, acts in the same way as selection does in life-assurance, and the effect of the selection wears off gradually; at the age of forty-five the mortality among married men being as great as that among bachelors. Crime is least rife among married people, and most common among those who have never married.

Births.—887,968 births were registered in England in 1876, being at the rate of 36·6 per 1000 of the population, the highest birth-rate on record, and 1·2 per 1000 above the average of the previous ten years. As might be expected, the mining and manufacturing counties show a greater birth-rate than the agricultural counties—thus Durham had a birth-rate of 45·2 per 1000, while that of Dorset gives only 28·5 per 1000. The illegitimate births numbered 41·594, being 4·7 per cent. of the total as compared with 5·5, the average of the previous ten years. The birth-rate in Scotland was 35·9 per 1000, in Ireland 26·4 per 1000.

Deaths.—In 1876, 510,315 deaths were registered in England, being 21·0 per 1000 of the population, a lower rate than any in the preceding twenty years. The rate in the Urban Registration Districts was 22·8, and in the Rural Registration Districts 18·6. The mean of the twenty-nine years 1847–75 was 22·5 for the whole country, 24·9 in urban districts, and 19·8 in rural districts. There were, in 1876, 108 deaths of males to every 100 deaths of females, the average being 104 to 100. The death-rate was less at every year of life than in 1875, probably on account of favourable atmospheric influences. The county with the highest rate of mortality was Lancashire (26·1 per 1000), that with the lowest rate the extra metropolitan portion of Surrey (16·2 per 1000). The proportional number of deaths of infants under one year of age was 146 for every 1000 births. In the large towns the proportion ranged from 142 in Portsmouth and 157 in London to 208 in Liverpool. The death-rate of children under five years was 63 per 1000 in England, ranging in the large towns from 69 in Norwich and 73 in London to 113 in Salford. The death-rate in Scotland in 1876 was the same as that in England, 21 per 1000.

The following table shows the mean annual mortality per 1000 in England and Wales since 1847:—

	England and Wales.	Urban Dists.	Rural Dists.
Mean of 4 years 1847–50	23.4	26.9	20.6
„ 5 „ 1851–55	22.7	25.5	20 1
„ 5 „ 1856–60	21.8	23.8	19.7
„ 5 „ 1861–65	22.6	24.7	20.0
„ 5 „ 1866–70	22.4	24 8	19 4
„ 5 „ 1871–75	22.0	24.0	19 3
Mean of 29 years 1847–75	22.5	24.9	19.8

The mortality in the British army in 1876 was 11·4 per 1000, or ·9 below the rate in the previous year. The mortality in the navy was 9·2 per 1000, or an increase of ·4 on the previous year. The mortality by drowning in the navy was 1·2 per 1000, and in the merchant service 11·4 per 1000. In the ten years 1866–75 these proportions were 2·4 and 13·6 respectively, figures surely forming a strong argument in favour of Mr. Plimsoll's legislation.

The following tables giving the V. S. of European states are taken from the Registrar-General's Report for 1878:—

TABLE A.

COUNTRIES.	Average Annual Rates per 1000 Population.

TABLE B.—AVERAGE ANNUAL RATES OF BIRTHS, MARRIAGES, AND DEATHS IN TEN EUROPEAN STATES IN THE FIVE YEARS 1872–76.

Country.	Average Annual Birth-Rate.	Average Annual Marriage-Rate.	Difference between the Birth and Marriage Rate.	Average Annual Death-Rate.
Hungary † . .	42.8	21.9	20.9	46.8
Austria . . .	40.3	17.6	22 7	32.3
German Empire	40.1	19.0	21.1	27.6
Prussia . . .	40.1	19 1	21.0	27.0
Italy	37.1	15.8	21.3	30.1
Netherlands .	36.2	16.6	19.6	24.2
England & Wales	35.9	17.1	18.8	21.7
Denmark . . .	31.2	16.3	14.9	19 6
Sweden . . .	30.7	14.2	16.5	18 7
France . . .	26.3	17.2	9.1	22.5

Cholera was epidemic in Hungary in the years 1873 and 1874. In the former year it raised the death-rate as high as 65·1 per 1000. The health of the Italian population is in an unsatisfactory state, and demands the attention of scientific men, municipalities, and the national government, particularly as to deaths by fever and among children. The small birth-rate in France should be a matter of anxiety to our neighbours.

* The mean annual rates for Spain are for the ten years 1861–70; those for Italy are for the ten years 1863–72.

† For Hungary the rates are for the four years 1872–75.

The following figures, from a table published by the Board of Health of New York, show the death-rate per 1000 in 18 cities in Europe and America during the year 1873:—

United Kingdom.		Europe.		United States.	
London . . .	22·83	Stockholm . .	30·45	New York . .	29·08
Liverpool . .	25·81	Vienna . . .	35·28	Philadelphia .	19·64
Birmingham .	25·28	Dresden . .	34·82	St. Louis . .	19·44
Manchester .	28·29	Munich . . .	45·48	Brooklyn . .	23·89
Glasgow . .	28·92	Rome . . .	34·14	Boston . . .	28·46
Edinburgh . .	21·97	Venice . . .	36·26	New Orleans .	37·52

Statistics of death are frequently delusive as regards the health of population of towns on account of inaccuracies in the census and in the death returns. The medical skill concentrated in large cities also attracts hosts of invalids, and a large proportion of bad lives from all parts of the country flock to the workhouses, asylums, and hospitals of the towns. The statistics of some cities show the benefits obtained from improved sanitary arrangements, drainage, a good water supply, &c., in diminishing the number of deaths from fever, phthisis, and the infant mortality. Thus in New York the number of deaths of children under 5 years of age was 52·99 per cent. of the total deaths in 1867, and only 48·28 per cent. in 1875. It is usually the case that when an excessive mortality has occurred in a district from severe weather or other cause, this is followed by a low death-rate, the weaker portion of the population having been diminished, and a larger proportion of tenacious lives remaining. The supplementary Report of the Independent order of Oddfellows (Manchester Unity), published in 1872, contains valuable statistics as to the rates of mortality and sickness prevailing among the provident working classes of this country, and the effect of locality upon mortality. It contains an analysis and tables embracing 1·321·006 years of life, in rural, town, and city districts.

It is found that half the members entering at eighteen in the rural districts live to sixty-six years of age, in the town districts to sixty-four, and in the city to sixty-two, while half the miners and colliers live to sixty-three. Out of 100,000 living at age eighteen in rural districts, 8308 more persons are living on attaining the age of seventy than in city districts. The expectation of life among Oddfellows is as under:—

Age.	Rural Districts.	Town Districts.	City Districts.	Miners and Colliers.
20	43·0	41·4	40·1	41·3
30	35·5	34 1	32·8	34 3
40	28 3	26·8	25 8	27 3
50	21·2	19·9	19·0	20 2
60	14·8	13 4	13·2	13·9
70	9·2	8 3	8 3	8 8

The average sickness experienced by Oddfellows in periods of ten years was as follows in weeks and days:—

	Rural Districts.		Town Districts.		City Districts.		Miners & Colliers.	
	Wks.	Dys.	Wks.	Dys.	Wks.	Dys.	Wks.	Dys.
From 20 to 30	7	6	7	6	7	3	11	1
" 30 " 40	10	0	10	0	10	0	14	5
" 40 " 50	15	1	14	2	15	2	21	6
" 50 " 60	27	2	25	4	29	6	35	5
" 60 " 70	56	0	60	4	70	1	83	0
From 20 to 70	116	2	118	2	132	5	166	3

Although, as age advances, the human constitution has a greater tendency to decay and greater liability to sickness, still in advanced life there is a greater power of enduring sickness.

The principle is clearly established that there is a widely different rate of mortality among different classes and ranks of society. Dr. Guy, in the 9th volume of the *Journal of the Statistical Society*, gives the average age attained by persons who have survived their fifty-second year thus:—Clergy, 74·04; gentry, 74·00; medical men, 72·95; lawyers, 72·78; navy, 72·62; commercial men, 72·32; literary men, 72·10; aristocracy, 71·69; army, 71·58; fine arts, 71·15; painters, 70·96; chemists, 69·71; kings of England, 64·12. According to the observations of Casper of Berlin, 42 theologians, 35 commercial men, 29 lawyers, and 24 physicians, out of every 100 of the age forty-two, reached the age of seventy.

Mortality from Alcoholism.—The statistics of mortality among persons of intemperate habits, compiled in Mr. F. G. P. Neison's *Contributions to V. S.* (3d ed. Lond. 1857), show a rate three times in excess of that of the general population. The expectation of life of people of intemperate habits was as follows:—

Age.		Expectation.	Age.		Expectation.
20	...	15·6 years.	50	...	10·9 years.
30	...	13·8 "	60	...	8·9 "
40	...	11·6 "			

The average duration of life after the commencement of intemperate habits among beer-drinkers was 21·7 years, among spirit-drinkers 16·7 years, and among those who drunk both beer and spirits simultaneously 16·1 years. While there are no statistics to show that the lives of total abstainers are longer than those of the temperate population, it is certain that large classes who cannot be called drunkards suffer from alcoholism. Publicans, for example, show an excessive mortality, as the following comparison of the annual rate of mortality among clergymen and Protestant ministers, and among publicans, taken from the 35th Annual Report of the Registrar-General proves:—

Ages.	Clergymen.	Protestant Ministers.	Publicans.
25-35	4·65	5·83	14·49
35-45	6 28	7·30	20·44
45-55	13 24	9·33	28·59
55-65	22·70	24 60	43·03

Vitebsk', a government of Western Russia, surrounded by Pskov, Smolensk, Mohilev, Minsk, Vilna, Courland, and Livonia. Area 17,438 sq. miles; pop. 888,727. The surface is in general hilly; in the depressions are numerous marshes and more than 2500 lakes, of which the largest are Lubahn, Rasno, Nevel, Sebesh, and Osvea. The chief rivers are the Duna, Mesha, Kasplja, Ulla, Drissa, and Evst. The soil is far from fertile, and the harvests, except under the most favourable conditions, are insufficient for the wants of the population. The principal occupations are agriculture, cattle-rearing, hunting, and fishing, besides tanning, weaving, and the manufacture of brandy and tobacco. Flax, linseed, hides, building-timber, and fancy wares are exported.—**V.**, capital of the preceding, lies on both sides of the Duna, 79½ miles N.W. of Smolensk by rail. It has more than 30 churches (6 Roman Catholic), 2 synagogues, an old palace, a theatre, a gymnasium, and an hospital, manufactures of mead and leather, and an active transit trade. Pop. (1875) 31,180.

Vitell'ius Au'lus, Roman emperor, the son of Lucius V., the consul (34), was born A.D. 15. At that dark period of Roman history vice and not virtue was the passport to royal favour, and the son like the father was a master of the arts of servile cringing and abject flattery. To these he owed his rapid rise and his favour with Tiberius, Caius Caligula, Claudius, and Nero. On the death of Galba he was proclaimed emperor by the soldiers at Köln, January 2, 69 A.D., and having crushed his rival Otho he secured undisputed possession of Italy. Though undoubtedly a man of low character, he did not proceed to extreme measures against the adherents of his rival. His chief passion was sensual gluttony, and he spent enormous sums of money in eating and drinking. Such a man was not likely to rule for long the troubled Roman world. Vespasianus (q. v.) revolted and was proclaimed emperor 1st July at Alexandria, and Antonius Primus declared for the new emperor and hastened into Italy at the head of a powerful force. He defeated the generals of V. twice and entered Rome on the 21st or 22d December 69. The fallen emperor was seized, dragged with every mark of ignominy through the streets, and murdered. See Tacitus, *Hist.* 2, 3; Suetonius, *V.*, and Tillemont's *Histoire des Empereurs*, vol. i.

Vitell'us, or **Yolk**, the name given to a part of the eggs or ova of animals. It varies in form and size in different eggs, some being 'large-yolked,' and others 'small-yolked.' The hen lays a large-yolked egg, the embryo being developed from a mere speck on the surface, named the *cicatricula* or tread.

The name *vitellin* was formerly given to the essential substance of which the V. was believed to consist, but this substance has been shown to be merely a form of albumen and casein, and not a special product of organic chemistry. The V. consists of highly-concentrated protoplasmic or albuminous matter, along with mineral substances, and it contains the nutritive matter from which the early tissues of the embryo are formed. In many respects the egg-yolk resembles milk in its nature.

Viter'bo, a town of Italy, province of Rome, 42½ miles N.W. of the city of Rome. It lies to the N. of the Ciminian forest, and is still surrounded by six fortifications erected by the Lombards. Of its 17 churches, the chief are the cathedral of St. Lorenzo, founded in the 12th c., and the much-venerated church of St. Rosa, containing the mummy of a saint. In the former, an Englishman, Pope Hadrian IV., made the Emperor Friedrich I. hold his stirrup in token of homage. Other interesting buildings are the bishop's palace, the Palazzo Publico, with a museum, and the Palazzo Vescovile, where between 1261 and 1281 six papal elections took place. V. used to be called 'the city of beautiful fountains and beautiful maidens.' Of the former the finest are the Fontana Grande (1206), and another in the court of the Palazzo Publico. There are some manufactures of leather, paper, playing-cards, lucifer-matches, soap, &c. In the neighbourhood are the Bulicame sulphur-springs, and 10 miles to the W. the great Etruscan cemetery city of Castel d'Asso. Pop. (1874) 16,326.

Vi'tex, a genus of trees or shrubs belonging to *Verbenaceæ*, scattered over the tropical regions of both hemispheres, a few reaching as far N. as the Mediterranean. The chaste tree (*V. Agnus castus*) derives its name from a supposed efficiency in banishing impure thoughts, for which reason it was used in Greece during the sacred rites of Ceres. The plants of this genus are aromatic, and the fruit of many has acrid properties. In India, *V. negundo* and *V. trifolia* are employed in native medicines as a bitter tonic. *V. altissima* is an important timber tree of S. India and Ceylon.

Vi'tious Intromis'sion, in Scotch law. See INTROMISSION.

Vito'ria, a town of Spain, province of Alava, near the Zadorra, 80½ miles S.W. of San Sebastian by rail. It stands on a hill, and consists of an old town (Villa Susa) and a new town—the former close, dirty, and irregular, the latter more widely and better built. The new town contains also fine promenades or alamedas, and a very large square (the Plaza Nuova) surrounded by an arcade. V. has 5 churches, including a Gothic cathedral. It manufactures steel, iron, leather, crockery, candles, &c., and has also a trade in corn and wine. Pop. 15,600. V. is memorable as the scene of a brilliant victory gained by Wellington and the Spaniards over the French under Joseph Buonaparte and Marshal Jourdan, 21st June 1813. The result of this victory—the crowning triumph of the Peninsular War—was the expulsion of the French from Spain.

Vitré, a town of France, department of Ile-et-Vilaine, on the little river Vilaine, 170 miles W.S.W. of Paris by rail, has an old castle, several churches, and a library, and manufactures linen and woollen goods. Pop. (1872) 8752. In the immediate neighbourhood of V. is the Château des Rochers, the residence of Madame de Sévigné.

Vit'rified Forts are ancient hill-fortresses, the walls of which are formed of stone perfectly or partially fused. Ruins of such structures abound on the crests of Scottish hills, vestiges of them are reported to exist in Ireland, one is known in the commune of Cledrau in France, and others in Bohemia. Vitrification is now generally admitted to have been performed designedly by the builders of the forts; but to what age (undoubtedly remote) they belong, and the motive for vitrification, are points that have not been satisfactorily solved. See Maclagan, *Hill-Forts, &c. of Ancient Scotland* (Edin. 1875), *Proceedings of Antiq. Soc. of Scotland* (vol. viii.), and Jamieson, *On the V. F. of Scotland* (2d vol. *Trans. of the Royal Soc. of Literature*).

Vitrin'ga, Campe'gius, a Dutch theologian, born at Leeuwarden, May 16, 1659, and educated at Franeker and Leyden. In 1681 he was called to Franeker as professor of Oriental languages, becoming in 1683 professor of theology, in 1693 professor of Church History, and in 1698 declining a most urgent call to Utrecht, on which occasion the university authorities of Franeker signified their sense of the honour he had done them by raising his stipend to 2000 thalers. He died March 31, 1722. V.'s name is specially associated with the exposition of the prophet Isaiah, his *Commentarium* on whom (1714-20) was probably without a rival till the publication of Ewald's *Dichter des Alten Bundes*. Of his minor writings, that on the 'Synagogue'—two editions of which were published during his lifetime in 1685 and 1696—perhaps most deserves mention.

Vit'riol is a commercial name for Sulphuric Acid (q. v.), and for several salts which that acid forms. The term V. was in common use among the alchemists, and was derived from *vitrium*, 'glass,' on account of the glassy appearance and transparency of copperas or green V. (the sulphate of iron). From copperas the alchemists prepared a strong sulphuric acid by distillation, whence also the acid was termed the *oil of V.* In addition to these there is yet commercially known blue V., which is a sulphate of copper, and white V., the sulphate of zinc (*zinci sulphas* of the Pharmacopœia) much used in medicine.

Vitru'vius, Poll'io, a Roman architect of the age of Augustus, celebrated as the author of the only Latin treatise on architecture which has come down to modern times. Of the details of his life but little is known, and that little is due to incidental allusions in his own work. That he was fairly well acquainted with Greek and Latin literature; that he served as a military engineer in Africa; that he obtained the direct patronage of the reigning emperor (Augustus, according to the consent of modern scholars, but Titus, according to an older opinion advocated by Newton); and that he composed his treatise in his old age to guide the judgment of his patron in matters of architecture—are the principal facts that are thus preserved. The *De Architectura* was probably completed B.C. 14. Besides the subjects strictly included under the title, it treats of water and aqueducts, sundials and machines. The style is a very bad one: at times perplexingly diffuse, and again as perplexingly curt, with an almost total absence of true literary grace; but the matter is of great value as being largely an epitome of treatises by Greek architectural writers. The authoritative MSS. are the Harleian of the 9th c. and the Gordianus of the 11th. The *editio princeps* was by Sulpicius at Rome between 1484 and 1492; and of recent editions the most noteworthy are those by Rode (Berl. 1800, 2 vols.), Schneider's (Leip. 1807, &c., 3 vols.), Statico (Udine 1825-30, 4 vols.), Rose and Müller-Strübing (Leip. 1867). There are English translations by W. Newton (Lond. 1771-91, 2 vols., with plates), and Wilkins (Lond. 1813, 2 vols.); French translations by Martin (Par. 1547), Perrault (Par. 1673), Tardie and Caussin (Par. 1839), and Maufras (Par. 1847, &c.); and German by Rivium (Nur. 1548), Rode (Leip. 1796), and Reber (Stuttg. 1864, &c.). See Baldus, *De Verb. Vitr. Signif.* (Augsburg 1614); Haubold, *Exercit. Vitr.* (Leip. 1821); Lorentzen, *Observat. Crit. ad Vitr.* (Gotha 1858), and Rohl, *Index Vitruvianus* (Leip. 1876).

Vi'try-le-Fran'çois, a town of France, department of Marne, on the Marne, 22 miles S.E. of Chalons by rail. The principal church (founded in the 17th c.), the Hotel de Ville (occupying the site of an old convent), and a bronze statue of Royer-Collard (q. v.) are its chief architectural features. There is a college, a library with 12,000 vols., and a technical school. It manufactures hosiery, hats, cloth, sugar, and leather, and has considerable trade in coal and corn. Pop. (1876) 7580. V.-le-F. was founded in 1544 by François I., 2 miles from the site of Vitry-en-Perthois, which had been burned the year before.

Vitto'ria, a town of Sicily, province of Syracuse, 43 miles W.S.W. of the city of Syracuse, was named after the mother of its founder, Vittoria Colonna. It has considerable trade in silk and cattle, and bees are extensively reared in the vicinity, but it possesses otherwise but little interest. Pop. (1874) 16,543.

Vitto'rio Amade'o I., Duke of Savoy, was born at Turin, 8th May 1587, and succeeded his father, Carlo Emanuele I., in 1630. The duchy was then embroiled with France, but in the following year (September 15, 1631) peace was signed at Cherasco, the conditions being the surrender to France of Pinerolo and one or two other important fortresses in exchange for Montferrato and Alba—an exchange very much to the advantage of France. Four years of peace followed, in which

Spain and France intrigued against each other for the alliance of Savoy. At last V.-A. quarrelled definitely with Spain on the question of his right to the title of King of Cyprus, and threw himself into the arms of France. He was at once nominated commander-in-chief of the French troops in Italy (July 1635), and in the next year overran the duchies of Parma and Modena, and gained a victory over the Spaniards on the Ticino. The jealousy of the French general, the Maréchal de Créque, impeded his movements, but in the succeeding year (1637) he again defeated the Spaniards at Montebaldone. About a month afterwards he died at Vercelli (October 7th).—**V.-A. II.**, son of Carlo-Emanuele II., was born 14th May 1666. He succeeded to the throne at the age of nine, the government being carried on under the regency of his mother, who attempted, even after he had come to years of discretion, to retain the reins of government in her hands. In this she was thwarted by the energetic character of her son, who, after rejecting a Spanish alliance which she had planned for him, married (9th April 1684) Anne of Orleans, a niece of Louis XIV. Compelled to choose a side in the struggle between France and Austria, he at first joined his arms with those of France, but, disgusted by the imperious conduct of Louis, who treated him as a vassal and demanded the most humiliating concessions, he joined the league of Augsburg in 1690. His territories were at once overrun by the French, and he was defeated in campaign after campaign, until, dissatisfied with the conduct of his allies, he concluded an advantageous alliance with France, August 29, 1696, by which Nice, Savoy, Pinerolo, and Villafranca were restored to him, along with 4,000,000 francs of indemnity. At the beginning of the war of the Spanish Succession he remained faithful to France, but, again enraged by the proceedings of Louis, he went over to the Austrian side in 1702. At first it seemed as if the French would become masters of his whole territory, but the failure of the siege of Turin by La Feuillade was a severe check to them, and he ultimately succeeded, with the aid of Prince Eugene, in driving them over the frontier (1706), and in the succeeding year he invaded the S. of France, but failed to take Toulon, and in fact accomplished little or nothing. Soon afterwards he followed the example of England in deserting the Austrian alliance, and by the treaty of Utrecht (January 11, 1713) he was confirmed in the possession of Savoy and Nice, and obtained in addition the island of Sicily, with the title of king. Spain did not, however, permit him to retain peaceful possession of this portion of her spoils, and he was forced to exchange Sicily for Sardinia. In 1720 he was formally recognised as king of Sardinia, and henceforth his reign was undisturbed by wars. He devoted himself with equal diligence and success to the amelioration of the condition of his subjects. He fostered agriculture and industry, especially the rearing of silkworms and the manufacture of silk; he encouraged education, placed the army and finances of his kingdom on an improved basis, and in 1723 promulgated an elaborate code of laws, known as the *Codex Victorianus*. Not a great general, though an intrepid soldier, he found in internal government and reform the true bias of his genius, and may be called in every sense the founder of the fortunes of his house and of his country. From some reason not adequately explained, he abdicated the throne, September 3, 1730, in favour of his son, Carlo Emanuele III., and retired into seclusion at Chambéry. In the following year he made two efforts to re-assume power, both of which were forcibly suppressed. He was held then in a sort of honourable confinement at Moncalieri, near Turin, until his death on the 30th of October 1732. See Ceratti, *Storia di V. A.* (Tur. 1856).—**V. A. III.**, son of Carlo Emanuele III. and grandson of the preceding, was born at Turin, June 26, 1726. He succeeded to the throne in 1773, and devoted himself to increasing and reforming the military establishments of the country, though at the same time he liberally promoted education and science within his dominions. Holding political theories of the most aristocratic type, and united by two alliances to the royal house of France, his dominions were crowded with *émigrés* from a very early period of the Revolution, and he prepared in 1792 to join the coalition and invade France. The tables were turned, however, by the French invasion of Italy, first under Scherer, and then under Bonaparte. His power was completely crushed, and he was compelled to sign a treaty (May 15, 1796) by which he gave up to France both Nice and Savoy. He survived his misfortunes barely six months, and died at Moncalieri, 16th October 1796, being succeeded by his son, Carlo Emanuele IV.

Vitto'rio Emanue'le I, King of Sardinia, second son of Vittorio-Amadeo III., was born at Turin, 24th July 1759. Under the title of Duke of Aosta he took part in the war of 1792-96 against the French. Succeeding to the throne on the abdication of his brother Carlo-Emanuele IV. (1802), he attempted to maintain a position in Rome and Southern Italy, but was forced to retreat to the island of Sardinia, where from 1806 to 1814 he maintained a state of mimic royalty. The events of 1814 restored him to his kingdom on the mainland, and by the end of 1815 he was master of the whole of Savoy, Nice, and Genoa. Failing, however, to appreciate the spirit of the times, he strove to re-establish absolute monarchy in its extremest form, commenced persecutions against the Jews and Waldenses, and rapidly alienated the affections of his subjects. Early in 1821, revolutionary movements began to make themselves felt, and on the 9th of March the revolution fairly broke out, and on the 13th, V. E., recoiling from the measures which would have been necessary for its repression, abdicated in favour of his younger brother, Carlo Felice. He died at Moncalieri, January 10, 1824.—**V.-E. II.**, King of Sardinia, and afterwards of Italy, was born at Turin, 14th March 1820. He was the son of Carlo Alberto, and bore, until his accession to the throne, the title of Duke of Savoy. He took an active part in the revolutionary movements of 1848, and in the campaign against Austria, until his father's abdication after the battle of Novara placed him upon the throne of Sardinia (March 23, 1849). His position was one of extreme difficulty, but he succeeded in proving that he possessed higher qualities than the mere personal bravery which he had evinced in the war. He concluded a peace with Austria, not so disadvantageous as the circumstances might have justified, and set himself to quell the disorderly factions of his state by a strict and conscientious adherence to the constitution granted by his father. Fortunately for him and Italy, his efforts were seconded by ministers of the highest order of political ability. Azeglio was the first head of the cabinet, but was succeeded in 1852 by Cavour (q. v.), who remained until his death the most valued adviser of the king. By its participation along with England and France in the Crimean War, Sardinia asserted its position among the nations of Europe; and when, in 1855, V.-E., accompanied by Cavour, visited the courts of Paris and London, he was everywhere received with distinction. Gradually the enthusiasm for Italian unity was growing and strengthening. The war of 1859, during which time V.-E. personally distinguished himself in the battles of Magenta and Solferino, placed Austrian Lombardy under his rule, though it lost him Nice and Savoy, which were ceded to France, while the Grand Duchy of Tuscany, which in 1859 had placed itself under his protection, was definitely added to his dominions in 1860. The same year saw a much more important acquisition, in the kingdom of Naples and Sicily, wrested from the Bourbons by the heroic enterprise of Garibaldi (q. v.). All Italy, except the Papal States and Venice, was now under one government, and on the 17th of March 1861 V.-E. received the title of 'King of Italy.' This unexpected success was followed by an equally unexpected loss in the death of Cavour, June 6, 1861. The ill-advised attempt of Garibaldi to add Rome to united Italy as he had added Naples, was repressed by the royal troops in the battle of Aspromonte (28th August 1862). In the spring of 1865 V.-E. made Florence his capital in place of Turin. In the next year war broke out between Prussia and Austria, and Italy cast in her lot with the former. Though defeated at Custozza by the Austrians, V.-E. refused to make a separate peace with Austria after the battle of Königgrätz, and procured by the treaty of Vienna (October 1866) the absolute cession of Venetia and entire expulsion of the Austrians from Italy. In December 1866 the French garrison evacuated Rome, but returned in 1867 when Garibaldi, at the head of his volunteers, again threatened the city. V.-E. incurred some unpopularity by his refusal to recognise and second the efforts of Garibaldi, who was entirely defeated by the combined French and Papal troops at Mentana (3d November 1867). The disasters of the great war of 1870, however, led to the final withdrawal of the French garrison, and the Pope was left without moral or material support. The Italian troops crossed the frontier of the Papal states early in September, and after a trifling conflict with the Papal Zouaves under General Kansler, entered Rome on the 20th September 1870. The temporal power of the Pope was thus destroyed, the unification of Italy completed, and Rome

made once more the capital of the Peninsula. On the 1st of July 1871 the government was formally transferred from Florence. The Quirinal became the royal residence, while the Vatican alone remained in the possession of Pius IX. (q. v.). From this culminating point of his career until his death, V.-E.'s reign was peaceful and undisturbed. In 1873 he visited the courts of Vienna and Berlin, and in 1875 received visits from the Emperor of Austria in Venice, and from the Emperor of Germany in Milan. He died at Rome, 9th January 1878, very shortly before the death of his life-long antagonist, Pope Pius IX. He was married in 1842 to the Archduchess Adelaide of Austria, by whom he had five children. The eldest son, Prince Humberto (born March 14, 1844), succeeded him; the second son, Prince Amadeo, Duke of Aosta, occupied the throne of Spain from 1870 to 1873. V.-E. and Cavour contributed in almost equal measure to the great work of Italian liberation and unification. A true patriot, and a wise, firm, and moderate ruler, V.-E., himself no contemptible statesman, appreciated and carried into action with admirable fidelity the profound statesmanship of his great adviser. The almost unvarying personal popularity of *Il Re Galantuomo* was of great effect, and he may be regarded altogether as one of those rare men who, though perhaps not possessed of the most brilliant or the most lofty qualities, seem born to suit their circumstances, and so to achieve the greatest possible measure of success. See a Life by Massari (2 vols. Mil. 1878), V. Bersegio, *Il Regno di Vittorio Emanuele II.* (vol. i. Tur. 1878), and A. Gallenga, *The Pope and the King* (Lond. 2 vols. 1879).

Vi'tus' Dance, Saint. See CHOREA.

Vivandière (Fr.), a female attendant on the regiments of Continental armies, who sells provisions and liquors. She wears a modified form of the regiment's uniform, and is usually a special favourite with the soldiers.

Viverr'a, a genus of Carnivorous animals, the type of the family *Viverridæ*, in which there are three premolar teeth on each side of the upper jaw, while four may be in each side of the lower jaw. In the genus V. itself the feet are five-toed, and the claws small and curved, the thumb-joint being small and raised. To this genus belong the civets, the rasse, &c.

Viv'ien de Saint Martin, Louis, one of the most learned and able representatives of geographical science in France, was born May 22, 1802, at Caen in Normandy, came to Paris when twelve years of age, and published a *Carte Électorale et Administrative* in 1823 and an *Atlas Universel* in 1825. He was one of the founders of the Société de Géographie (1822), constructed the first georama in Paris (1826), and became successively editor of the *Annales des Voyages* (1842-56), the *Athenæum Français* (1852, &c.), and the *L'Année Géographique* (1863-76). Of the separate works which bear witness to V.'s unflagging industry and steady devotion to his favourite science, it is enough to mention *Études de Géographie Ancienne et d'Éthnographie Asiatique* (1850-54), *Sur la Géogr. et les Populations prim. du N.-O. de l'Inde d'apres les Hymnes Védiques* (1860), *Le Nord de l'Afrique dans l'Antiquité Grecque et Romaine* (1863), *Hist. de la Géogr.* (1873), *Nouveau Dictionnaire Géogr. Univ.* (2 vols. 1877 *et seq.*), *Atlas Universel* in 110 maps (1877 *et seq.*), *Dictionnaire de Géogr. Historique* (1878, &c.). V. is one of the honorary presidents of the Société de Géographie, from which he has also received the great gold medal, a vice-president of the Société d Éthnologie, and a member of the Berlin Academy of Sciences.

Vivisec'tion, the art and practice of experimenting upon living animals for the purpose of physiological discovery and medical research. The act of V. is never practised for the mere purpose of acquiring manual dexterity in operating; such dexterity is acquired by the student from practice on the dead subject. The subject of V. has become one of the 'burning questions' of late years, and recent legislation has been enacted with the view of placing the practice under restriction. The effect of the late enactments chiefly lies in the direction of preventing unqualified persons from experimenting on the living subject, and providing for the licensing by the Home Secretary of all persons and places where V. is carried on. The laboratories are duly inspected by Government inspectors, and returns of experiments are required by the recent Act, which is limited to Vertebrate animals in its scope. To the question—Is 'V.' necessary for physiological research, and therefore for the due furtherance of the healing art? there can be but one and that an affirmative reply. The answer to the query—'Is V. justifiable—even if necessary?' will depend on the attitude taken up with regard to the relations of the lower animals to man and to human wants and requirements. It is obvious that the whole question of the legality and morality of V. turns upon our construction and definition of the right to inflict pain, and also upon our opinion of the nature and amount of pain inflicted. Man inflicts pain on lower animals (1) in his search after food; (2) in the pursuit of pleasure; (3) in his repression of animal-species which threaten to annoy him; and (4) for the purpose of physiological research. That pain is inflicted upon the animal world in very many and varied ways, and that pain and death form the natural heritage of lower as well as higher life, are plain facts. Amongst animals themselves, bloody war and torture are carried on in the struggle for existence which pervades creation. Popular opinion recognises that man even in the pursuit of pleasure may inflict pain and torture upon lower animals, although in the case of the sportsman's torture of hares, foxes, deer, pigeons, &c., there exists but the gratification of tastes which bear no relation to the aims set before the scientific investigator in V.—namely, the advance of science and the cure of disease. But the subject of V. must also be considered in relation to pain and its nature. The standard of an animal's sufferings is certainly not that of human pain. Yet in discussions on V. the idea is invariably taken for granted or even expressed that the pain endured by the experimentation must be equal to human suffering. But, so far as physiology teaches, there is no warrant for the belief that a brain and nervous organisation inferior to that of man is capable of feeling or thinking with human power. Pain, in short, is relative to the organisation of the animal, and exists (when judged by human standards) in a gradually declining proportion as we descend in the animal series.

To the question, is V. absolutely necessary for the furtherance of medical research? the physiologist will unhesitatingly reply in the affirmative. How, for example, can the cure of *diabetes* be successfully accomplished, save by experiments on living animals with the view of determining how glycogen is formed in the liver? What knowledge of the cure of this disease we do possess, is founded upon Claude Bernard's vivisectional researches on the latter subject; and the case of diabetes and its cure is but one of many which might be cited with the view of showing the impossibility of curing disease rationally and successfully without recourse to experimentation on living animals. Sir Charles Bell could never have discovered the functions of the posterior and anterior roots of the spinal nerves without the aid of V.; and the latter discovery has laid the foundation of all the knowledge we possess regarding the action of the nervous system. The physiologist of to-day has no need to resort to V. to demonstrate already known facts and truths which are accepted without question by all. In the class-room V. is as needless as in the laboratory it is necessary. The whole question, indeed, is one which may be well summed up in the words of Professor Michael Foster, who in arguing that if medical science is worth preserving, and if human life be therefore worth saving, V. is necessary to further both ends—'Take away from the art of medicine all that with which physiology has enriched it, and the surgeon or the physician would be little better than a mystery-man or a quack vendor of chance-gotten drugs. Take out of the present system of physiology all that has been gained by experiments on living animals, and the whole structure would collapse, leaving nothing but a few isolated facts of human experience.'

Vizag'apatam' (*Visakha-patta-nam*='the land of Visakha,' the Hindu Mars), the chief town of the district of the same name, in the Madras Presidency, British India, on the sea-coast, 380 miles N.E. of Madras; pop. (1871) 32,191. It stands at the head of a bay, on a small river, and carries on a large coasting trade. One of the points of the bay, called the Dolphin's Nose, rises 1500 feet above the sea. A British factory was settled here in the middle of the 17th c. There are special manufactures of cotton cloth, gold and silver embroidery, silver, ivory, and horn ornaments. The exports in 1874-75 were valued at £117,000, chiefly piece-goods, oil-seeds, and sugar; the imports at £50,000. The *district* of V. occupies the strip below the E. Ghauts S. of Ganjam and the wild hill country behind; area 18,344 sq. miles; pop. (1871) 2,159,199. The crops are rice, oil-seeds, sugar-cane, and tobacco. The hills rise to the height of 5000

feet. Sugar is extensively manufactured under European superintendence. This tract formed one of the N. Circars occupied by the British in 1767, and includes the semi-independent States of the Jeypur Agency (q. v.).

Vizeu, a town of Portugal, province of Beira, 50 miles N.N.E. of Coimbra. It is old, irregularly built on a hill, and contains a cathedral with fine paintings, also a college, hospital, and theatre. There are two large squares, in one of which a great market is held in September. Among many Roman and Moorish remains is a Roman camp, the *Cava de Viriatho*, where Jun. Brutus was defeated by Viriathus. Pop. 7000.

Vizianágram, a town in the district of Vizagapatam, Madras Presidency, British India, 35 miles N. of Vizagapatam, and 12 miles from the sea-coast; pop. (1871) 20,169. In the fort is the palace of the Rajah of V., a Rajput family which figures largely in the early history of the British in Madras. The present Rajah, who usually resides at Benares, is the most Anglicised of Indian princes, and well known for his charity and munificence. The challenge shield annually shot for by the Lords and Commons at Wimbledon is his gift. He is a K.C.S.I., and a member of the Viceroy's Council. His income is over £100,000 a year, and he pays a fixed revenue to Government of £50,000. He is hereditary warden of a celebrated shrine of Siva at Kotiphali on the Godavery river. The area of his estate is 431 sq. miles; pop. (1871) 203,476.

Vizier' (Arab. *wazîr*, 'he who bears a burden'), the title of a high political officer in Mohammedan states. It is said to have originated with the first Abasside Caliph in 750 A.D., and to have been introduced among the Ottoman Turks in the reign of their second sultan. Subsequently, the title of V. Azim or Grand V. was adopted for the prime minister at Constantinople, where the rank of ordinary V. has grown common. In 1877 the title of Grand V. was abolished, but has since been introduced. At the court of the Mogul Empire at Delhi V. was the highest office; and the title ultimately became hereditary in the dynasty that ruled in Oude as Nawaub V.

Vizzi'ni, a town in Sicily, province of Catania, 28 miles S.S.W. of the city of Catania, has handsome streets and several fine buildings, including a college, hospital, and library. Pop. (1871) 14,831.

Vlaar'dingen, a town of the Netherlands, province of S. Holland, on the New Maas, 8 miles W. of Rotterdam by rail. It has one Catholic and one Protestant church, the latter with fine sepulchral monuments. V. is the chief centre of the Dutch herring fishery, which in 1876 employed 57 vessels and 855 men, and has large docks, shipbuilding, and considerable trade. Pop. (1870) 8575.

Vladi'mir, a government of Russia, surrounded by Jaroslav, Kostroma, Nijni Novgorod, Riazan, Moscow, and Tver. Area 18,862 sq. miles; pop. (1870) 1,259,923. The surface consists of level and undulating plains, and the soil is fertile. About 32 per cent. is covered with pine-forests. The whole government is drained by the system of the Oka, which flows for 82 miles through V., and receives from the left the Kliasma, with its navigable tributary, the Tesa. The largest lake is Plechejevo, which receives the Trubesh, and sends the Great Nerl to the Volga. The principal crops raised are buckwheat, rye, oats, potatoes, pulse, flax, cherries, and onions. In industrial activity V. ranks next to Moscow and St. Petersburg. Its manufactures include paper, crystal, glass, chemicals, brandy, cotton, linen, and woollen fabrics, and metal wares, chiefly knives, chisels, locks, gimlets, and reaping-hooks. The forests yield timber, pitch, and tar. A special industry of V. is the manufacture of Icons, to the value of 1,200,000 roubles annually.—**V.**, capital of the preceding, on the Kliasma, 110 miles E.N.E. of Moscow by rail, has twenty-eight churches, two monasteries, handsome government buildings, &c., and manufactures of Icons. Pop. (1875) 16,422.

Vladi'mir I., Czar of Russia, commonly called **V. the Great**, or **Saint V.**, was the son of the Grand-Duke Sviatoplav by a woman of low condition, and great-grandson of Rurik. His father assigned to him the government of Novgorod, dividing the rest of the empire between his two legitimate sons, Jaropalk and Oleg. In 977 Jaropalk quarrelled with Oleg and killed him, and V. would probably have met the same fate had he not fled to the Varangians (q. v.). Two years later he returned with an army, overcame Jaropalk, and remained sole master of the empire, having his capital at Kiev. He now set himself both to extend and to consolidate his dominions, which were little better than a collection of tributary states, scarcely subject to any real control. He enlarged his boundaries from the Black Sea to the Baltic, and appears to have had an intention of welding his empire into a homogeneous mass through the agency of a common religion, in which he tried to combine the Slavonian and the Finnish superstitions. In 988, however, an event occurred which altered his schemes entirely. He had already five wives and almost a thousand concubines, but while besieging the Christian city of Cherson, in the Crimea, he conceived the idea of demanding the hand of Anna, the sister of the Byzantine Emperors Constantine and Basilios. Through the agency of this princess, known in history as Anna Romanovna, he was converted to Christianity. His subjects, who had already been prepared for Christianity by intercourse with the Greeks, followed his example. The Scriptures had already been translated into Slavonic by Cyrillus and Methodius, and Russia soon became a Christian country. V. was now as enthusiastic in his Christian virtues as he had formerly been in his heathen vices. He could scarcely be induced to sanction capital punishment, he exercised a lavish charity, built churches and monasteries, and promoted not only the Christianisation but also the civilisation of his subjects. He died at Beresyx in 1015 at a great age, and divided his empire among his twelve sons. The Russian Church has canonised him, and given him a rank equal to that of the Apostles, and the famous 'V. order' was founded in his honour by the Empress Catherine II. in 1782.—**V. II.**, called **Monomachus** after his maternal grandfather, the Emperor Constantine Monomachus, was born in 1052, and succeeded to the empire in 1113, in opposition to the ordinary Slavonic rules of inheritance. Though not free from some of the barbarisms of his age, he did much for Russia by the establishment and enforcement of just laws, and the consolidation of the internal affairs of the empire. He was married to Gida, daughter of King Harold of England, and his granddaughters married the kings of Norway and Denmark, so that the famous Valdemar of Denmark, probably so named in his honour, was his great-grandson. He died at Kiev, May 19, 1126, leaving behind him a long 'testament' full of instructions to his descendants, which presents a curious picture of contemporary manners and opinions.

Vliess'ingen. See FLUSHING.

Vode'na (Gr. *Bodena*), a town of Turkey, in Macedonia, 46 miles W.N.W. of Salonica, at the foot and on the summit of a rock over which an affluent of the Mavroneri (Karasmak) falls. It manufactures tobacco, and has some woollen and cotton spinning. Pop. 10,000. V. occupies the site of the ancient *Edessa*, the residence of the Macedonian kings before Philip.

Vo'gel, Eduard, an African traveller, was born at Krefeld, March 7, 1820. His father was Johann Karl Christoph V., afterwards director of the public school at Leipzig, and his sister is known in German literature as Elise Polko. Devoting himself to astronomy, V. studied at Leipzig and Berlin, and in 1851 became assistant to Hind in London; but in 1853 he was called to take command of an expedition from England intended to co-operate with Barth and Overweg in Central Africa. In January 1854 he reached Lake Chad, in December joined Barth near Zinder, and in 1855 pushed S. to Yacoba and the Benue. Before the close of the year he entered the kingdom of Wadai, where in the early part of 1856, probably on 8th February, he was brutally massacred near Abeshr. See his sister Elise Polko's *Erinnerungen an Einen Verschollenen* (Leip. 1863).

Voghe'ra, a town of Italy, province of Pavia, on the Staffora, 81 miles E. of Turin by rail. It was fortified by Giovanni Galeazzo Visconti, and an old castle still exists built by him towards the end of the 14th c. The church of St. Lorenzo, founded in the 11th c., and remodelled in 1600, is the only building of importance, but the town is handsome and well laid out. There are considerable manufactures, chiefly of cloth and hats. Pop. (1874) 15,500.

Vogler, George Joseph, usually called **Abt** (that is Abbot or Abbé) **V.**, a German composer, was born at Würzburg 15th June 1749. The Elector of Bavaria, Karl Theodor,

enabled him (1773) to prosecute his musical studies at Bologna, Padua, and Rome, and on his return to Germany he was appointed kapellmeister (1772) and court chaplain at Manheim (1775). After several years of travel in France, Spain, Greece, and Africa, he was for a short time kapellmeister at Stockholm, and then we find him in succession at Copenhagen, Altona, Berlin, Prague, and Vienna (1803-5). At Darmstadt, where he settled in 1807, he had Weber and Meyerbeer among his pupils; and he died there 6th May 1814. V. was a voluminous composer both of sacred and secular music, and he contributed to the critical literature of his art, but both his pieces and his books have passed into the background. In his own day, while some considered him a man of highest genius, others denounced him as a charlatan. Charlatan or genius, he has been immortalised in English literature by a powerful poem in Browning's *Dramatis Personæ*, in which he is represented as saddened by the irrevocable vanishing of all music, and then gladdened by the thought of an after life in which it will become eternally possible to recall or re-create.

Voice (Fr. *voix*, Lat. *vox*), the production of sound, as distinguished from *speech*, which is a further modification of V. to produce articulate sounds representing ideas. V. is produced in the *larynx*, or *organ of V.* situated at the top of the trachea or windpipe. The larynx is a gristly and elastic box or cavity, containing two elastic folds of mucous membrane—the so-called *vocal cords*. These cords are so attached to the cartilages of the larynx and to muscles that they may be stretched or relaxed, shortened or lengthened, and otherwise altered so as to produce changes in the sounds produced by their vibration. The chief cartilages of the larynx are the *thyroid cartilage*, covering the front of the organ, and the *cricoid cartilage*, a circular structure supporting the two *arytenoid cartilages*. The vocal cords are attached posteriorly to the base of the arytenoid cartilage, and to the back part of the thyroid; hence movements of these cartilages necessarily affect the cords; whilst the movements of the cricoid cartilage affecting the arytenoids which rest upon it, will also alter the position of the V.-producing structures. By aid of an instrument consisting of deftly-arranged mirrors, and named the *Laryngoscope* (q. v.), we are enabled to discover the mode of action of the vocal cords in the living subject. The observation of the larynx proves that the inferior vocal cords are the true organs of V.; the *false vocal cords* being the name given to the folds of mucous membrane placed above the true vocal cords already mentioned. The expired air passing over the edges of the cords throws them into vibration and produces the V. If the windpipe be opened below the larynx, the voice is destroyed, but returns when such an opening is closed; whilst if the opening be made above the *glottis* or entrance to the larynx, so that air still passes through the larynx, the V. is uninjured. So also, if the nerves supplying the vocal cords be injured, V. ceases. In the dead body V. may be produced by forcing a current of air through the larynx; and this occurs even after removal of the false vocal cords. In the production of V., those structures which aid in placing the vocal cords in a parallel position may perhaps be credited with the largest share of importance. The *glottis* or opening of the larynx in ordinary quiet breathing is triangular in shape, becoming, however, slightly narrower at each expiration. In taking a deep inspiration, the glottis dilates widely and becomes somewhat lozenge-shaped. When V. is produced, it narrows, and the edges of the arytenoid cartilages become opposed, the vocal cords being thus brought parallel with and closer to one another, whilst they are drawn tighter than before. The higher the note of V. produced the tenser are the cords drawn. Thus the range of V. depends very largely upon the power possessed of causing tension of the cords. By the laryngoscope, the vocal cords are seen to be brought forward, and are readily seen during the production of a high note; whilst they are depressed and overarched by the epiglottis when deep notes are produced. The hinder part of the aperture of the glottis does not appear to be concerned in the production of V.; a fact which shows that the arytenoid cartilages and their movements have no share in this function.

In the physiology of V. three kinds of notes are recognised: (1) those which possess one pitch, or nearly so, as in speaking; (2) the alternations of high and low pitch, witnessed in sounds of crying or in the howling of animals; (3) the true musical sounds, where the nature of each sound depends on the number of vibrations. The distinction between noise and musical sound depends on the definite vibrations of the latter and the indefinite vibrations of the former. The qualities of V. found in man number four—two recognised as the attributes of the male sex, *tenor* and *bass*, and two belonging to the female V., *soprano* and *contralto*. Primarily the difference between male and female voices consists in the fact that they begin and end at different notes in the musical scale. About an octave of difference thus exists—the lowest note of the female averaging an octave higher than the lowest of the male. About four octaves is the total range of male and female voices together. The bass V. is strongest in its low notes; the tenor extending higher than the bass, but the latter being most powerful in its low notes. What is technically named *timbre*, in reality constitutes the difference between the various voices, the expression having reference to the quality as well as to the compass of the notes of each. The different pitch of voices is due to the varying length of the vocal cords, those of men as compared with those of females being as three to two. The *timbre* is found to depend on the form and shape of the larynx, which is larger in men than in women, and possesses more extensive walls. Before *puberty* the voices of boys resemble those of women; and it is noteworthy that in eunuchs who have been castrated prior to puberty the V. remains in the boyish state. The vocal cords become longer after the period of puberty has been attained, while in old age the cartilages become ossified, and nervous power becomes deficient, these conditions producing the unsteady V. of aged persons. The production of *falsetto-notes* as distinguished from *chest-notes* appears to depend upon some obscure and ill-understood modification of the action of the vocal cords. Müller conceives that falsetto-notes are produced by the vibration of the inner borders only of the cords, while Diday and others attribute the production of these notes to vibrations of air passing through the aperture of the glottis. Among the subsidiary but in many ways important circumstances which aid in modifying the V., are the amount or degree of vibrations of the cords; the nature of the nervous control of these structures; the observance of the larynx, throat, and mouth-cavities; the freedom of respiration, &c. The mind also has an undoubted influence in the regulation of the V. An inability to distinguish notes or tunes naturally exists in many persons, and this mental condition naturally interferes with the culture of the V.

Voir'on, a town of France, department of Isère, on the Morge, 13½ miles N.W. of Grenoble by rail. It has extensive manufactures of iron and steel goods, cloth, paper, leather, &c. Pop. (1876) 11,064.

Voi'ture, Vincent, born at Amiens in 1598, studied at Paris, and by a copy of verses (1614) securing the patronage of Gaston d'Orléans, became comptroller of that prince's household. Through a fellow-student, the Comte d'Avaux, and his own gay wit, he gained an entrée to the choicest Parisian circles, notably to the Hôtel de Rambouillet (q. v.), of which he was looked on as the laughing, as Balzac its serious, philosopher; and in 1634 he was chosen one of the early members of the French Academy. Despatched to Tuscany (1638) to announce the dauphin's birth, he passed on to Rome, there to receive the membership of the Academia dei Umoriste; and on his return became the king's maître d'hôtel (1639), from this and from other appointments drawing a revenue of 18,000 livres. Gambling his only passion, he lived on gallant and frivolous to the last, dying in Paris, 26th May 1648. The rondeaux of V. are the best among their kind; of his sonnets one gave rise to the great literary feud of Jobelins and Uranistes; his *Lettres* (ed. by Roux, 1856) were regarded as models of the epistolary art. Yet somehow they all have lost their point; the charm and prettiness ascribed to them can no longer be seen, though it is allowed that modern French prose owes much of its present facility to V. See Ubicini's edition of V.'s *Œuvres* (2 vols. 1855), and Demogeot's *Tableau de la Littérature Française au XVIIe Siècle* (Par. 1859).

Volca'noes, or **Burn'ing Mount'ains**, are hills which from a vent or 'crater' eject smoke and flames, stones, or lava upon the surrounding country. The first sign of the appearance of a new volcano is said to be the opening of a rift or chasm in the earth, from which issue masses of steam or vapour accompanied by many loud explosions. Lava, or molten rock, then appears flowing over the margin of the chasm, and often also

discharged by a sudden outburst into the air, along with clouds of smoke and showers of stones and dust. The lava, according to Sir Charles Lyell, 'is forced up by the expansive power of entangled gaseous fluids, chiefly steam or aqueous vapour, exactly in the same manner as water is made to boil over the edge of a vessel when steam has been generated at the bottom by heat.' That portion which has been shot into the air, for the most part 'separates into fragments, and acquires a spongy texture by the sudden enlargement of the included gases, and this forms *scoriæ*, other portions being reduced to an impalpable powder or dust. The showering down of the various ejected materials round the orifice of eruption gives rise to a conical mound in which the successive envelopes of sand and scoriæ form layers, dipping on all sides from a central axis. In the meantime a hollow called a *crater* has been kept open in the middle of the mound by the continued passage upwards of steam and other gaseous fluids.' The crater usually exhibits a round orifice occupying the apex of the conical mountain, and has very generally one side higher than the other whenever a steady wind has directed the falling material towards one particular quarter. The great internal heat and exhaustion of the contained material frequently lead to the falling in of a crater, in which case there is produced a great trough or hollow, at the bottom of which is the new vent. Such hollows, often of vast size, are known by the Spanish name of Calderas.' An entirely new crater, appearing at a short distance from the old one, is also a not uncommon phenomenon.

From the crater the sides of the mountain slope regularly and gradually downward on all sides, and the dust and ashes and scoriæ of which they are formed soon decompose and weather into a rich and fertile soil, peculiarly adapted for the growth of the vine and certain other plants. Thus Santorini in the Ægean Sea is famous for its marvellous fertility, and for the wine and even cotton produced on it; and the grapes which grow upon the slopes of Mount Vesuvius produce the wine well known to travellers as 'Lachrymæ Christi,' or 'Tears of Christ.' It was declared by Leopold von Buch, and his statement was accepted by many other geologists, that lava rolling down the slopes of a mountain ere it consolidated invariably assumed a porous or vesicular structure, and only formed a dense and solid rock when deposited on a surface horizontal or nearly so. Accordingly, pushing this theory further, its upholders said, when they found a mountain flanked by strata of compact, nonporous lava, that those beds could not have been formed in such a situation, but must have been laid down at an angle not exceeding 4 or 5 degrees, and upheaved subsequently to their ultimate position. For mountains formed after this manner von Buch proposed the name of 'Elevation Craters,' and cited as a typical example the Isle of Palma, one of the Canary group, a great, inactive volcano, with a huge crater surrounded by sheer precipices 2000 feet in height. Sir Charles Lyell, however, who visited the island for the special purpose of examining into the grounds of this hypothesis, found no reason to suppose that the mountain had been formed in other than the usual manner.

The lava, besides being vomited forth from the mouth of the crater, also very frequently makes its escape by rifts or secondary openings in the mountain-side. Thus, during the great eruption of Hecla in 1783, an immense mass of molten lava burst from a great fissure, and formed a fiery river which flowed on for a distance of about 50 miles, and then divided into two branches, each of which pursued its way to the sea for a nearly similar distance. The greatest breadth attained by this huge torrent was 15 miles, and the extreme depth 100 feet. The fine dust or powdered scoriæ being shot up to a vast height in the atmosphere, may be carried by the wind to an enormous distance. The volcanic dust from Hecla has fallen on more than one occasion in the Orkney and Shetland Islands, notably in the eruption of 1845; and in 1835 the ashes from Cosequina are said to have been wafted to Jamaica, 700 miles away. Besides the solid matters which are ejected, such as stones, dust, and lava, sulphureous vapours, carbonic acid, and other gases are frequently exhaled. Dead animals and birds have been picked up on Vesuvius during eruptions, and the valley of the Upas Tree, in Java, owes its deadly effects, not to the tree itself, but to the noisome vapours which issue from an extinct volcanic crater, and prove destructive to every animal that ventures near.

Submarine V. are by no means of rare occurrence, though their eruptions seem to be as a rule of short duration. Voyagers have occasionally observed smoke arising from the sea, and shortly afterwards a new island begins to show itself above the level of the waves. The Canary Islands, and many of the scattered islands of the Pacific, owe their origin in this manner to submarine eruptions. An island, known as 'Grahame's Island,' thus appeared in 1831, in the Mediterranean, but the loose materials of which it was composed were soon disintegrated and washed away by the sea.

The suddenness with which volcanic manifestations take place is often very remarkable. The famous outburst of Vesuvius in 79 A.D., by which Pompeii, Herculaneum, and other cities were overwhelmed, took place, with very little warning, after a period of inactivity so long that the volcano had been looked upon as extinct. In the last century the hill near Naples known as Monte Nuovo was upheaved in a single night, and in 1759 a tract of country amounting to about 4 sq. miles was suddenly raised to a height of 5000 feet in the great plateau of Mexico. The most important European V. are Vesuvius, Etna, and Hecla. On the first of these there is a well-equipped observatory, in which Professor Palmieri resides, and takes constant observations, which cannot fail to increase our knowledge of the conditions of eruptions, and also probably to give timely warning of impending outbursts. The Lipari or Æolian Islands, off the Sicilian coast, known anciently as the Insulæ Vulcaniæ, and Santorini in the Archipelago, are also more or less active. The chief island in the former group, namely Stromboli, is called by our sailors the Lighthouse of the Mediterranean; by day, nothing but a column of smoke is seen ascending from it, but this at night has the appearance of a pillar of fire, being brightly illuminated by the reflected glow from within the crater. In the department of Auvergne, in Central France, are very numerous extinct volcanic mountains, the highest summits being Puy-de-Dome, Mont Dor, and Cantal, all of which have been inactive since the Miocene age. Jan Mayen is an isolated volcanic island situated in 70° N. lat.

In the S. American Continent numerous V. are found, from Tierra del Fuego northwards through the chain of the Andes, the principal centres being in Chili, Peru, and Quito. Central America has several large craters, such as Casiguina and Popocatepetl, while the Rocky Mountain ranges have, N. of Mexico, few active but many extinct and dormant V. Hence the chain of volcanic activity is continued through the Aleutian Islands to Kamschatka, where the chief volcano has the lengthy name of Klutchewskaja, and the series is prolonged down the whole length of the western coasts of the Pacific, by Japan, the Philippines, the Sunda Islands, and New Zealand. Among the isolated and oceanic V. we may enumerate Hawaii and the Marquesas in the Pacific, the Azores, Teneriffe, and the Cape Verd group in the Atlantic, Jebel Tarr or Mount Sinai on the Red Sea, and Mount Erebus in the Antarctic, in lat. 77° S. See Scrope, *V. and their Phenomena* (new ed. Lond. 1872); and Fuchs, *Vulkanen und Erdbeben* (Leip. 1875).

Vole (*Arvicola*), a genus of *Rodentia* (q. v.) belonging to the Rat and Mouse family (*Muridæ*). The voles differ from their more familiar neighbours by possessing curiously-folded molar teeth. The ears are rounded and short, and the tail is also short. The incisors, as in mice and rats, number 2 in each jaw, the premolars 2, and the molars 4. The best-known example of the V. is the Water V. (*A. amphibius*), popularly named the 'Water Rat.' Its average length is about 13 inches, the tail attaining a length of 3 or 4 inches. It breeds twice yearly, and produces from 4 to 5 young at a birth. The colour is a chestnut brown mixed with grey on the upper parts. The water V. feeds upon a variety of substances, chiefly vegetable, but that it devours fish is doubtful. The Campagnol or Short-tailed Field Mouse (*A. arvalis*) is a true V., which often swarms in immense multitudes in certain districts and destroys large quantities of grain and the young shoots of trees. An excessive production of voles occurred in the New Forest about 1813–14, when large numbers were captured in pits dug for their reception. The Campagnol is also named the Short-tailed Field Mouse to distinguish it from the 'Long-tailed' species, which is a true mouse. It also receives the name of 'Field V.' Its average length is 5 inches, and the colour a ruddy brown above and grey beneath.

Vol'ga (Tartar *Etil, Itil, Atel*, 'bountiful;' Slav. *Bolga* or *Vg* Finnish, *Rau*; the anc. *Rha* or *Darus*), the largest river of Europe, rises in the central Russian government of Tver, near

the Dwina, about 200 miles from the Gulf of Finland, flows S.E. through several small lakes, receiving the Selicharovka from Lake Seliger, then S.E. past Rsjev to Subzov, where it turns N.E., passing Tver and Rybinsk, then S.E. through the governments of Jaroslav, Kostroma, Nijni Novgorod, and Kasan, passing Nijni Novgorod and Kasan, and receiving from the right the Oka, and from the left the Mologa, Kostroma, Unsha, and Wetluga. At Kasan it turns S., receives from the left the great Kama and the Samara, and from the right the Sura, separates the governments of Simbirsk and Saratov from Samara, and passes the towns of Simbirsk, Samara, Sysran, Wolsk, and Saratov. At Sarepta it turns sharply to the S.E. and flows in that direction to the Caspian, which it enters by 8 principal and 200 smaller mouths, forming a delta 68 miles in breadth. Besides those named, about 100 smaller tributaries join this giant river, which with its affluents has a drainage area of 517,120 sq. miles, waters 22 governments, and measures from its source to its mouth 2290 sq. miles. Its breadth at Tver is 705 feet, at the mouth of the Mologa 1542 feet, above the influx of Kama 4920 feet, and opposite the mouth of the Kama nearly 5 miles. The course of the V. is very slow, its total fall is only 896 feet, and its channel is comparatively shallow, its greatest depth being 85 feet. The V. is free from ice for 200 days in the year, in Kostroma, Jaroslav, and Kasan for 152. Steamers ply regularly upon its waters between Tver and Nijni Novgorod, Kasan and Astrakhan; and from Nijni Novgorod by the Kama to Perm, by the Oka to Riazan, by the Ufa to Ufa, and by the Unsha to Ugor. The three great canal systems of Vishni-Volotchok, Tichvin, and the Marien canal, connecting the V. with St. Petersburg, and the canal of the Duke of Wurtemberg joining it with the Dwina, make an unbroken water-way between the Baltic and the Caspian Sea. A canal to join the V. with the Don, between Zarizyn at Katchalinsk, was projected by Peter the Great, but was never executed. Its purpose is now effected by the Zarizyn-Kalatsch Railway. The V. has extensive fisheries, chiefly of salmon and sturgeon. See Legrelle, *Le V.; Notes sur la Russie* (Par. 1877).

Volhyn'ia, a government of Western Russia, bounded N. by Grodno and Minsk, E. by Kiev, S. by Podolsk, W. by Austrian Galicia and the Polish governments, Lublin and Sjedlez. Area 27,738 sq. miles; pop. (1870) 1,719,890. The surface in the N. is uniformly flat and in some districts marshy; in the S. it is covered with offshoots from the Carpathians, the summits of which are 1200–1300 feet high. Many rivers rise among the hills in the S., among them the Turia, Styr, Goryn, and Teterev to the N., and the Sbrutch to the S. The rivers belong to the system of the Pripet and Teterev, affluents of the Dnieper, or to that of the Bug, which for 112 miles is the boundary between V. and Poland. The N. half of the government, known as *Polesje*, contains many small lakes. The largest unbroken swamp is that which stretches from the frontier of Grodno to the river Pripet, covering 386 square miles. The soil in the S. is exceptionally fertile, and yields abundant crops of corn, beet-root, tobacco, hops, pulse, and fruits. The chief manufactures are sugar, paper, leather, chemicals, glass, pottery, cloth, and metal wares. The principal exports are, corn to Odessa, Galicia, Poland, and through Pinsk to Prussia; cattle, hides, horn, and wool to Galicia and Poland; and timber, which is carried to the Vistula, and floated down to Warsaw and Danzig.

Voli'tion. See WILL.

Voll'ey, a simultaneous discharge of small-arms. A similar discharge of artillery is called a Salvo.

Vol'ney, Constantin François Chasseboeuf, Comte de, a French traveller, philosopher, and politician, was born 3d February 1757 at Craon in Anjou. He lost his mother at an early age, and was almost neglected by his father, who was a lawyer of some repute. He was educated at the colleges of Ancenis and Angers, where he highly distinguished himself, and at seventeen years of age went to Paris to continue his studies. His father, who had 'emancipated' him, or renounced his paternal authority, gave up to his own control the little inheritance of 1110 francs a year which he had from his mother, and made him exchange the name of Chasseboeuf, which was distasteful to him, for that of Boisgirais. He himself afterwards assumed the name of V. At first he devoted himself to medical studies, but soon turned his attention mainly to history. An essay, *Sur la Chronologie d'Hérodote*, which he published in 1781, threw open to him the philosophic salons of Paris, but in the same year he received another small inheritance of 6000 francs in all, which he determined to devote to travel in the East. After careful 'training' for the endurance of hardships and privations, he started on foot for Marseille in the end of 1782, carrying his little store of money in a belt on his person. He spent nearly three years in the East, seven months in a convent on the Lebanon studying Arabic, and the rest of the time travelling in Lower Egypt and Syria. On his return he published his *Voyage en Egypte et en Syrie* (Par. 1787), which achieved a great success, exhibiting as it did great powers of minute observation and philosophic reflection. His celebrity thus began just as the Revolution was breaking out. The Royal government had appointed him director of agriculture and commerce in Corsica, where he wished to try some agricultural experiments, but being elected to the States General by the province of Anjou, he gave up his post before he had even commenced his duties. On the dissolution of the National Assembly, however, he retired to Corsica, where he purchased an estate near Ajaccio, and began his experiments. Here he made the acquaintance of Bonaparte, and is said to have predicted his greatness. Driven from Corsica by Paoli's insurrection, he returned to France, and once more took part in political affairs. His attachment to the Girondin party very nearly cost him his head during the Reign of Terror. He was imprisoned for ten months, and would certainly have been executed but for the Revolution of Thermidor. The publication of the work by which his name is now principally remembered, *Les Ruines ou Meditations sur les Révolutions des Empires* (Geneva 1791), had meanwhile added to his fame, and he was appointed (1794) professor of history in the École Normale. On the breaking up of this institution a year later he went to America, where he got into a quarrel with Priestley, and also with the United States Government. On his return to France in 1798 he at first favoured the designs of Bonaparte, though he refused the Ministry of the Interior after the Brumaire Revolution. He became a member of the Senate, but soon went into opposition, as Bonaparte's despotic tendencies became more apparent, though in 1808 he accepted the title of Comte. On the Restoration V. was raised to the Chamber of Peers, where he maintained a position as a partisan of moderate liberty. His last work was a brochure on the occasion of the coronation of Louis XVIII. at Rheims, entitled *Histoire de Samuel, Inventeur du Sacre des Rois* (Par. 1819). He died at Paris, 25th April 1820. His principal works, in addition to those mentioned above, are his *Considerations sur la Guerre des Turco et de la Russie* (Lond. 1788), in which he predicted the French occupation of Egypt, *La Loi naturelle, ou Catéchisme du Citoyen Français* (Par. 1793), in which he attempted to establish an order of the universe on a purely theistic basis, *Leçons d'Histoire* (Par. 1799), *Tableau du Climat et du Sol des États-Unis d'Amérique* (Par. 1803), *Supplément à l'Hérodote de Larcher* (Par. 1808), *Simplification des Langues Orientales* (Par. 1759), *L'Alphabet Europée applique aux Langues Asiatiques* (Par. 1819), and *Discours sur l'Étude philosophique des Langues* (Par. 1820). He appears to have been among the first to recognise the importance of philology as a means to the study of ethnology and 'prehistoric history.' See Bossange's *Notice sur la Vie et les Écrits de V.* (Par. 1821), and Berger's *Études sur V.* (Par. 1852).

Vo'lo, a seaport of Turkey, in the vilayet of Janina, stands at the head of the Gulf of V., 37 miles S.E. of Larissa. A small place with a population of only some 3000 souls, it has an excellent harbour, which in 1874 was entered by 2417 vessels of 161,840 tons, the exports (cereals, silk, tobacco, oil, &c.) amounting to £997,699, the imports to £426,842. At V., during the late Thessalian insurrection, Mr. Ogle, the Athens correspondent of the *Times*, was murdered by Turkish irregulars, 2d April 1878.

Volog'da, a government of Great Russia, S. of Archangel and N. of Kostroma. Area, 155,498 sq. miles. Pop. (1875) 1,003,039; of whom 897,000 are Russians and 172,000 Syrjanians, a Finnish tribe. Its surface is mostly a vast plain, becoming hilly towards the S., and mountainous towards the E., where the Urals expand into a wild highland tract. Only in the S. of the government is agriculture possible. Most of the province lies in the great forest zone, and 87 per cent. of its surface is covered with pine woods. V. is drained chiefly

by the Dwina (q. v.) and its tributaries towards the White Sea; the Petchora flows through the N.E. part to the Arctic Ocean. Hunting and fishing are almost the only employments in the major part of this government. Salt, skins, and iron are exported. —**V.**, the capital of the government, on the V., a tributary of the Suchona, 281½ miles N. of Moscow by rail. It is an old wide town, largely built of wood, the residence of the governor and a bishop. It has 54 churches, a theological seminary, a gymnasium, and several monasteries. There are extensive manufactures of sailcloth, leather, soap, matches, linen-cloth, glass, white-lead, and jewellery. Pop. (1875) 17,233. V. was founded in the 12th c. During the 16th it was a great centre of trade with England, and many English settled here. Though less important now as a trade emporium, much merchandise still passes through the place to the White Sea ports.

Vol'sci, a people of ancient Latium, whose language proves them to have been a branch of the Umbro-Sabellian stem, and who, holding the Pontine Marshes, the valley of the Liris, and the Volscian Hills, extended from the sea-coast to the Samnite frontier. With Rome they seem from an early period to have waged constant wars, with one of which the legend of Coriolanus (q. v.) is associated, but Rome had entirely subdued them by 338 B.C., from which date they vanish as a separate race from history. See Corssen, *De Volscorum Lingua* (Naumb. 1858).

Volsk, or **Voljsk**, a town of Russia, government of Saratov, on the Volga, 80 miles N.E. of Saratov. It has 5 churches, a technical school, normal school, &c. There are large quays along the river, and trade in tallow and skins with St. Petersburg, in fruit with Nijni-Novgorod, and in corn with Astrakhan and Rybinsk, is carried on. A great market is held in autumn. Pop. (1875) 31,269.

Vol'ta, Alessan'dro, a famous natural philosopher, was born at Como, in N. Italy, 19th Feb. 1745. In 1774 he was appointed to the chair of natural philosophy in the University of Pavia, which he resigned in 1804, after making the electrical discoveries which laid the foundation of what is still known as *Voltaic electricity*. The nature of these discoveries is noticed under other articles; here we need only enumerate them, referring to the particular heading under which each is treated. In 1775 he invented the *electrophorus* (see ELECTROSTATIC INSTRUMENTS), the principle of whose action was first satisfactorily given by Dr. Ingenhouz (*Phil. Trans.* 1778), and in 1782 his researches led him to the construction of an electric condenser and an electrometer, or, more properly, an electroscope. The discoveries of Galvani, which that philosopher regarded as indicating the existence of animal electricity, were traced by V. to their true cause, thereby opening up a new field of scientific research (see *Electrokinetics* under ELECTRICITY, and VOLTAIC BATTERY). His last years were spent in his native town, where he died of fever, March 5, 1826. His collected works were published at Florence (3 vols. 1816). A statue of V. was unveiled at Pavia on April 28, 1878.

Volta'ic Batt'ery is any arrangement of different substances which in virtue of their electric relations and mutual chemical action are capable of generating electric currents. At the contiguous surfaces of any two different substances in contact, a difference of electric potential exists, which depends upon the surfaces in contact and the temperature at which the contact is made. In a circuit of simple conductors, such as metals, kept all at one and the same temperature, the sum of these differences taken all round is equal to zero—in other words, the contact forces balance, and there is no current possible. Where, however, one of the substances in circuit is an *electrolyte* or decomposable liquid, experiments show that the contact forces do not balance, that there is a resultant electromotive force to which the current is proportional. The energy of the current is derived from the chemical action which invariably accompanies the generation of currents. Thus, in the earliest form of V. B., namely, Volta's Pile, a single element consists of copper and zinc discs separated by a piece of moistened paper or cloth. When the circuit is completed by joining the copper and zinc with a wire, a current begins to flow, while simultaneously the zinc is oxidised, the water decomposed, and hydrogen given off at the copper surface. Heat is always evolved when oxide of zinc is formed; but, in the pile, part of this energy of combustion first appears as energy of an electric current, ultimately, of course, after a longer or shorter period, being transformed into its equivalence of heat. Electrolysis (q. v.) is thus the invariable accompaniment of voltaic action. Polarization, due to the accumulation of the products of decomposition upon the electrodes, is also a frequent accompaniment, and if not in some way prevented has the effect of diminishing the electromotive force of the cell. In Smee's battery, the one product, oxide of zinc, is dissolved in the dilute acid which forms the electrolyte, while the other, hydrogen gas, readily escapes from the surface of the finely-divided platinum which forms the positive pole. The double liquid cells are, however, the most constant in electromotive force, since the liquids at once dissolve the products which appear at the respective poles. Thus in Bunsen's cell, which consists of zinc and carbon electrodes immersed in dilute sulphuric and strong nitric acid respectively, the liquids being separated by a porous diaphragm so as to be in contact with mixing, the sulphate of zinc formed at the negative or zinc pole is retained in solution, and similarly with the nitric and nitrous oxides formed at the positive or carbon pole. The Grove cell differs from the Bunsen cell in having platinum instead of carbon for the positive pole. The most constant of all known cells is the Daniell. It consists of zinc and copper electrodes, immersed in semi-saturated sulphate of zinc and saturated sulphate of copper respectively. Sulphuric acid may be substituted for the sulphate of zinc. When the cell is working the zinc is eaten away to form sulphate of zinc, which dissolves, while at the same time copper separates out from the sulphate of copper, and is deposited in the copper pole. Neither pole then changes character, so that there is no tendency to polarization. See Wiedemann's *Galvanismus and Magnetismus*, and Cumming's *Theory of Electricity*.

Voltaire' (originally FRANÇOIS MARIE AROUET) was born at Paris, probably November 20, 1694. Hardly expected to survive, he was 'ondoyé' or privately baptized. But he grew up a bright and precocious boy, and at the College Louis le Grand, where he was placed when about ten years of age, he delighted his Jesuit teachers by displays of unusual ability in the literary exercises of the schools. At seventeen V. declared he wished to be nothing but a man of letters, and while for some time he nominally attended the legal classes, his head was full of odes and epics and tragedies. His prudent father, to remove him from the temptations of Paris, sent him to Holland as secretary to the Marquis de Châteauneuf, but the marquis soon sent V. back again, guilty of having fallen hotly in love with a Mademoiselle Dunoyer (1714). At length in 1716 an unexpected interruption occurred in his career. Accused of being the author of a satire on the Duc d'Orleans, he was for a time banished from Paris; and not long after his return from exile at Sully-sur-Noir, another piece, *Les j'ai vu*, really written by Lebrun, being ascribed to him, the Duc made him a prisoner in the Bastille (16th May 1717–10th April 1718). Towards the close of 1718 his *Œdipe* was brought on the stage and obtained a brilliant success; and though he was again banished to Sully in 1719, he continued for the next six or seven years to extend his influence both in society and in letters. He laid the foundations of a considerable fortune, he was on intimate terms with dukes and princes, and he began to be in favour at court. After a second imprisonment in the Bastille he was set at liberty within a few weeks on condition that he left the country for a time, and embarked for England in the end of August 1726. He had already become acquainted with Lord Bolingbroke in France, and during the three years of his English residence (1726–29) he found congenial associates in Locke, Shaftesbury, Toland, and Clarke. Rapidly acquiring a free command of the English language, he absorbed the influences then at work in our literature, and in all his after writings the traces of his indebtedness are abundant. Shortly after his return to France he printed anonymously at Rouen the *Lettres Philosophiques*, in which he sought to enlighten his countrymen in regard to the English and their methods of thought and life; but his praise of the foreign principles and procedure was regarded by the government as an audacious attack on itself, the book was burned by the public executioner, and the author was obliged to seek safety from arrest in Lorraine (May 1734). In 1733 he had met with the Marquise du Châtelet, a lady of unusual intellectual ability and scientific attainments. With her he now found an asylum, and till her death their lives continued to flow in a common, if not always a peaceful, channel.

V. in his time had formed attachments and friendships with many women, but none of them except this were of permanent moment in his career. In the Marquise du Châtelet he found a vigorous and co-operative sympathy with his work as a man of letters. When she died in 1749, though her death in childbed was the result of an intrigue with a younger admirer, V.'s grief was excessive. Meanwhile his authority in literature had been rapidly extending; he had received a seat in the French Academy (1746), and for years he had been the correspondent and guide of the young Friedrich II. of Prussia. An invitation to Berlin, frequently repeated since 1737, he at length accepted in 1750, and nothing could have been more flattering than the welcome he received from his patron and pupil. But it was not long before the mutual felicitations grew less enthusiastic: a thousand little disagreements disturbed the intercourse of the two monarchs. The story becomes a pitiable succession of squabbles and recrimination. V. wished to be trusted with Friedrich's political schemes, and Friedrich wisely trusted him only with his verses. There was an academy at Berlin, of which Friedrich was naturally proud, and which V. as naturally turned into ridicule. Against Maupertuis, one of the Academicians, V. wrote his *Diatribe du Docteur Akakia*, one of the most brilliant and bitter of his satires, and the diatribe was by Friedrich's orders burned by the hangman. At length V. bade a wrathful adieu to Berlin (26th March 1753), but to his intense chagrin and exasperation he was arrested at Frankfurt on the Main by Friedrich's agent Freytag, and obliged to deliver up certain royal manuscripts and other mementos of his Berlin residence. The hostility of the clerical party in France was by this time thoroughly aroused against him, and at length in 1755 he found it prudent to seek safety in Switzerland, finally settling at Ferney or Fernex, a little French village on the Genevese frontiers. For the next seventeen or eighteen years he remained the patriarch of Ferney and the cynosure of intellectual Europe. His niece, Madame Dénis, kept house for him. Visitors and guests were abundant; staid burgers from neighbouring Geneva, savants and princes from far and near. Yet no old man was ever so laborious. V. was no recluse from the world's doings, but could make his power felt far for justice and right, as the incident of *Calas* (q. v.) proves. At length in 1778 V. was persuaded to return to Paris. Welcomed by universal gratulation of nobles and people, fêted and flattered till he felt as if he were 'being choked with roses,' the old man found his strength give way under the excitement and effort, and in the night of May 30-31 he breathed his last. V.'s literary activity was simply marvellous. His correspondence alone was labour for a lifetime. He was master of a style of lithe and sinewy structure in which grace and strength are the common outcome of the most accurate adjustment and interplay of parts. He is never feeble, never bombastic; always forcible, never forced. To the drama, the department in which he gained his first great success, V. frequently returned; the author of *Œdipe* became the author of *Mariamne* (1723), *Zaire* (1732), *Alzire* (1736), *L'Enfant Prodigue* (1736), *Mahomet* (1741), *Mérope* (1743), *Le Café ou l'Écossaise*, and a score of other pieces, tragic and comic. In this department of French literature he comes immediately after Corneille and Racine. While he was still in the first flush of his dramatic success he solicited Minerva in a more ambitious task; French literature had dramas of immortal strain, but every epic as it rose had withered and was forgotten. The *Henriade* (first published without the author's authority in 1723, and afterwards at London in 1726) was accepted by his contemporaries as an achievement worthy to rank the poet with Homer and Virgil; but though it is still remembered and read, it is relegated to a very secondary position. His notorious *Pucelle* is really a more powerful poem, for the great master of mockery was here in his element, though he was unfortunate enough to throw despite on a name which has since risen into the highest heaven of a nation's admiration. If we turn to V.'s prose writings we find the same variety of form; histories, romances, tales, dialogues, essays, pamphlets, satires. His tales, such as *Candide ou l'Optimiste*, *Zadig*, and *L'Homme aux quarante Écus*, are from a literary point of view among the happiest of his efforts. In his hands history became no longer a book of kings or a chronicle of wars, but a study of laws, arts, manners, and movements of thought. With the partial exception of *Charles XII.* (1731), this is true of all his historical works of importance—*Siècle de Louis XIV.* (1752), *Essai sur les Mœurs* (1757), *Histoire de Russe* (1759-63), *Précis du Siècle de Louis XV.* (1768), and *Histoire du Parlement de Paris*. They are based on laborious investigations, and as far as possible on what we now call original research. In the eyes of his sterner critics V. is only a great *persifleur*; but through all his writings, from tragedy to jeu d'esprit, one increasing purpose runs, to emancipate the human mind from the ruthless domination of superstition. He was not an atheist. He believed as dogmatically in God as he disbelieved in Moses and Christ. But superstition he identified with the church, and the church with Christianity; and against this triune abomination he fought ceaselessly at once with secret and with open war. He had no great constructive ability, and in room of the vast theologico-metaphysical structure which he undermined, he was content to put up with very flimsy wicker-work. On the other hand, he battled nobly for justice and freedom. Against religious persecution his whole soul rose in impassioned revolt. Though he grievously misunderstood and indeed hardly recognised many of the noblest aspirations and ideals of the race, to the great cause of humanity he was not untrue, and the world, whether it thank him or not, owes him no small debt of gratitude. It would be vain to attempt a list of the editions of his *œuvres*. The most noted are Beaumarchais and Condorcet's (70 vols. Kehl 1784-89), Beuchot's (70 vols. Par. 1829-34), and Avenel's (1867-73). His *Œuvres Inédites* appeared in 1862. V. was not only voluminous himself but he has been the cause of others being voluminous also. For details, see Quérard, *Bibliographie Voltairienne* (Par. 1841). Among the principal works dealing with the facts of V.'s life are Duvernet, *Vie de V.* (Par. 1796); Condorcet, *Vie de V.* (Geneva 1787); Peignot, *Recherches sur les Œuvres de V.* (Dijon 1817); Durdent, *Histoire Littéraire de V.* (Par. 1818); Lepan, *Vie Publique, Littéraire, et Morale de V.* (Par. 1819); Paillet de Warcy, *Histoire de la Vie et des Ouvrages de V.* (2 vols. Par. 1823); Longchamp et Wagnière, *Mémoires sur V. et ses Ouvrages* (Par. 1825); Bungener, *V. et son Temps* (Par. 1851; Eng. trans. Lond. 1854); Ars. Houssaye, *Le Roi V.* (Par. 1858); L'Abbé Maynard, *V. sa Vie et ses Œuvres* (2 vols. Par. 1867); Pompery, *La Vrai V. L'Homme et le Penseur* (Par. 1867); John Morley, *V.* (Lond. 1872); and Desnoirresterres, *V. et la Société Française au XVIIIe Siècle* (8 vols. Par. 1867-1878). This last work is the fullest of all the lives, and it has been crowned by the French Academy. The separate volumes are so many monographs, as vol. i. *La Jeunesse de V.*; vol. ii. *V. au Château de Cirey*. M. Desnoirresterres has also published *Iconographie Voltairienne: Histoire et Description de ce qui a été publié sur V. par L'Art Contemporaine* (Par. 1879).

Volterr'a, a town of Italy, province of Pisa, 5 miles from the railway station of Saline, which is 48½ miles S.E. of Leghorn by rail. It is surrounded by ancient walls with great gates, the chief of which is the Porta all' Arca. The cathedral, opened in 1120, contains fine marble sculptures; the baptistery of St. Giovanni and the church of St. Francesco have valuable frescoes and other paintings. The citadel, founded in 1343, with a more modern addition called Il Masteo, is now used as a penitentiary. In the Palazzo Communale is the Museo Civico, founded in 1208, and containing a valuable collection of Etruscan antiquities and a library. V. has also remains of baths and an amphitheatre. Large alabaster works are the main industry of the town. At Saline are important salt-works and borax springs. Near V. are also several Etruscan burying-places and a subterranean labyrinth. Pop. (1874) with district, 13,402. The ancient *Volaterræ* (Etruscan *Velathræ*), V. was one of the twelve great Etruscan cities. The Romans took it in 474 B.C., and it became an important *municipium*, resisting a siege by Sulla for two years.

Vol'tri, a town of Italy, province of Genoa, on the Gulf of Genoa, 10 miles W. of Genoa by rail. It contains the fine church of Madonna dell' Acqua, and numerous villas, which indeed line the coast from Genoa. V. has numerous paper factories. Sulphur, which abounds in the neighbourhood, is employed in the manufacture, and is supposed to improve the quality of the paper. The sulphurous springs (Acqua Santa and Acqua della Penna) are frequented by invalids suffering from skin disease. There is also a good harbour and some trade. Pop. (1871) 5943. Here, on 18th April 1800, the Austrians were defeated by the French under Massena.

Volumet'ric Anal'ysis, a name given in chemistry to a method of analysis, in which the quantity of a substance present

in a given solution is estimated by the amount which must be added of a given standard solution so as to produce and complete a characteristic reaction. The principle of the method, which was first suggested by Gay-Lussac, is based upon the laws of equivalence (see ATOMIC THEORY), and its success depends on the existence of a characteristic and easily recognised reaction. See ACIDIMETRY and ALKALIMETRY for particular cases which are included under the method.

Vol'untaryism is the designation of that system of Church polity which denies to the State the right of interfering in matters of religion, either by patronage or control; which asserts that the Church should be supported only by voluntary gifts, and that its members should be left entirely free to regulate its affairs. This definition would be accepted so far as it goes by all who claim to be called Voluntaries. There are many, however, who would not be satisfied with it. Looking rather at the rights of the subjects of the State than at the duties and privileges of the members of the Church, they would define V. as the principle which demands religious equality and liberty of conscience for all citizens. They are not satisfied with such equality as is secured by the abolition of tests, and the free admission of qualified candidates to offices of honour and emolument, irrespective of creed. They demand that all churches should be placed on an equal footing in the eye of the law, and that the exceptional privilege of establishment and endowment accorded to those who adhere to the creed and ritual recognised by the State should cease; and assert that all legislation which in any way furthers one form of religious opinion rather than another is inequitable. They maintain that liberty of conscience is as really infringed by the compulsion which exacts support for a creed or a form of worship of which the taxpayer does not approve, as by the persecution which compels him to profess the creed or to conform to the ritual. They are therefore as firmly opposed to the teaching of religion in State-supported schools as to the maintenance of State-supported churches. Nor is their opposition confined to such legislation as enacts the payment of taxes for religious purposes. They deem it inconsistent with the voluntary principle to enforce, for example, the keeping of the Sabbath on the ground that it is a divine ordinance. They would not deny to the civil authority the right to arrange, in view of the physical and moral well-being of the community, that one day in seven should be observed as a day of rest; but they would reckon it a violation of the rights of conscience to base the enactment on the authority of the Mosaic or Christian law.

There are some voluntaries, however, who do not carry the principle they profess so far as those whose position we have indicated. They limit its application to the relation between Church and State. They believe that the Church is a divine institution, which by the ordinance of its Founder is forbidden to enter into alliance with the civil power. They hold that He has laid it as a permanent and universal obligation on His people to maintain and extend the Church, and that this provision is exclusive of aid contributed by legal enactment. They believe that it is as inconsistent with the spirituality of the Church to accept the support of the public exchequer, as to permit its doctrine to be propagated by force. They hold that the only security which the Church can have for that freedom from control which they deem essential to her healthful existence, is that she undertake the whole responsibility of providing for her own support. Voluntaries of this class do not necessarily object to such recognition of religion by the State as does not interfere with the free and unaided action of the Church. They believe it to be consistent with their principles that the legislature should give effect to the teaching of scripture; and they do not deem it unlawful to provide for religious instruction in schools supported by public rates. These positions are maintained by some professing V., but it is doubtful whether they are perfectly consistent with the principle.

Both in England and Scotland V. was adopted as a practical means of Church support before it was accepted as a theory. The Nonconformists of England in the 17th c., and the Seceders of Scotland in the 18th, did not separate from the established churches because they disapproved of the connection between Church and State. They were driven out because they could not conform to the prescribed ritual, or acquiesce in the decisions of the Church courts. In their state of separation they maintained for a considerable time the principle of establishments, till gradually, through experience of the freedom they had found beyond the pale of the national Church, and of the adequacy of the Voluntary system to support the ordinances of religion, they came to accept V. as a theory. The largest of the Voluntary churches of Scotland still asserts the lawfulness of establishments; and in the next largest, V., though all but universally professed, is not a term of communion.

Volunteers' are part of the reserve military forces of Great Britain, available for defence against invasion. The oldest volunteer body in the country was the Honourable Artillery Company of the City of London, instituted in 1485, and revived, after a period of suspension, in 1610. This force took the side of Parliament in the Civil War, and was of great assistance. An organisation of V. on a grand scale took place towards the end of last century. In 1793–94, on a threatened invasion from France, a force of nearly half-a-million of men sprang to arms, and 150,000 were actually reviewed at one time by George III. These corps were gradually disbanded on the cessation of the danger, and the only reserve force existing during the following half-century was the militia. Two volunteer corps were formed in 1857, one in London (the Victoria Rifles), and one in Devon. In 1858 considerable alarm was felt in this country as to the intentions of France and the position of the nation; its small standing army contrasted with the great military organisations of the Continent caused general anxiety. The result was the volunteer movement, which was inaugurated with complete success. A War Office order, signed 12th May 1859, sanctioned the formation of volunteer corps, and a force of nearly 150,000 men was in existence in the course of a year. In 1860 the Queen reviewed 18,450 volunteers in London, and a still larger number in Edinburgh. In the same year, Government, which had hitherto left the movement to the public spirit of the community, appointed paid adjutants and drill instructors, and established a staff of inspectors. In 1870 the number of V. had increased to 170,000, and according to the statement of the Secretary of War in moving the army estimates in March 1879, the enrolled V., including the staff, were at that date 203,213 strong.

The volunteer force is regulated by the Volunteer Acts of 1863, 1868, 1869, the Regulation of the Forces Act of 1871, and Orders in Council which may be issued from time to time. It is localised in corps, a certain number of which are attached to the brigades for each subdistrict of the army. It cannot be employed to put down civil disturbance, but it may be embodied upon invasion, or an apprehension of invasion. This step must be communicated to Parliament; or, if Parliament be not sitting, then to the country by an Order in Council.

A company of V., sixty in number, with a captain and two subalterns, may be formed in any place. Four such companies are entitled to a major-commandant, and six companies constitute a battalion, for which Government appoints a military officer as adjutant. If one corps have more than twelve companies, it is usual to divide it into two battalions. A number of detached companies in a scattered district may be grouped together to form an administrative battalion. The adjutants and sergeant-instructors are subject at all times to the Mutiny Act—the other V. only when actually embodied. All V. must take the oath of allegiance, and must be at least seventeen years of age. They can leave the force on giving fourteen days' notice. The required height for the artillery is 5 feet 6 inches, for other corps 5 feet 3 inches, and the required width of chest 32 inches. V. may be (1) *honorary*, entitled to wear the uniform although not enrolled; (2) *non-efficient*, enrolled but still learning the volunteer drill and discipline; and (3) *efficient*. An efficient volunteer is defined by Order in Council, August 1874 (substituted for schemes of 27th July 1863 and 15th October 1872). He must have attended a certain number of drills, and be certified by the commanding officer and adjutant of his corps to have a competent knowledge of his duties. It is according to the number of efficients that the Government aid to volunteer corps is regulated, a capitation grant of 30s. annually being voted for each. In addition, a special grant of £2, 10s. is given for each officer and sergeant who holds a certificate of proficiency obtained by a severe examination, and small allowances are made in cer-

tain districts to cover the cost of attending battalion drills. Adjutants, sergeant-instructors, and arms are supplied by the State. The volunteer expenditure of the Government for 1878–79, exclusive of arms and ammunition, amounted to £512,400.

The *National Volunteer Association*, established in 1859, holds annual meetings in July of about a fortnight's duration at the camp at Wimbledon, and the shooting prizes offered by it have stimulated the production of a splendid body of marksmen throughout the country. The subscription to the association is £1, 1s. annually, or £10, 10s. for life. There are about 100 sub-associations. At the Wimbledon Meeting of 1878 the prizes numbered 1753, and amounted in value to £14,684. To win the Queen's Prize of £250 is the highest ambition of a marksman. Among the most interesting contests are those for the International Trophy and the Elcho Shield, the former shot for by 3 twenties and the latter by 3 eights, representatives of English, Scottish, and Irish V. Owing to an alteration in the rules confining the competition for International Trophy to Wimbledon instead of its taking place in the ground of the last winner, the Scottish team have ceased to compete for it. The Elcho Shield has been won nine times by England, and four times each by Scotland and Ireland. The Irish representatives are chosen from Irish volunteer corps in Great Britain, as though the subject has been repeatedly mooted, the volunteer acts have not yet been extended to Ireland. At Shoeburyness there is an annual gathering of the Volunteer Artillery Association (the artillery of the force numbering about 30,000 men) similar to the rifle meeting at Wimbledon. Each corps is entitled to select its own uniform. V. will probably be armed before long with the Martini-Henry rifle, like the regular army. An abortive attempt was made in 1878 in view of Eastern complications to raise a volunteer force for service abroad. The Government declined to recognise such a body.

Volu'ta, a genus of Gasteropodous Mollusca (q. v.), the type of the family *Volutidæ*, having a turreted or convoluted shell, the shell-aperture being notched in front. There is no speculum, and the foot is large and well developed. To this family also belongs the genus *Mitra*. In the genus *V.* itself the spine of the shell is shut, and the *columella* or central pillar or axis of the shell is plaited. In the allied genus *Mitra* the mouth to the shell is small, and the shell itself spindle-shaped. Many species of both genera occur in modern seas: the genus *V.* first occurs in the Chalk in a fossil state.

Volute'. See Column.

Vol'vox, a genus of minute unicellular *Algæ* which congregate into colonies. The best-known species is *V. globator*, found in stagnant water, in which it swims about with a rotatory motion. The colony consists of a variable number of plants united into a spherical mass just visible to the naked eye, by a gelatinous investment from which the cilia project. The mass is constantly breaking up into free factors, which in turn pass through a similar divisional process. This non-sexual reproduction takes place to an unlimited extent. The sexual reproduction is by antheridia and volgonia. Only a small number of cells in a colony are sexual. The vospheres are large and surrounded by a gelatinous cell-wall, the vogonium. The spermatozoids are developed in smaller cells, the antheridia, and fertilise the vosphere by penetrating the gelatinous wall. An allied genus is *Gonium*, in which the colony assumes a quadrangular shape.

Vol'vulus (Lat. *volvere*, 'to twist') is the term used in surgery to signify a twisting of the intestine, producing obstruction to the passage of its contents, and strangulation of the part involved. Three forms of V. are described by surgeons—(1) when a portion of intestine becomes twisted on its own axis, a condition which may occur in the ascending colon; (2) when a portion of the mesentery is twisted into a cone dragging the intestine with it, a condition which may occur in the small intestine; (3) when a portion of intestine with its mesentery is coiled round another portion of intestine, so as to compress it and close the passage. The sigmoid flexure or the cæcum may form the axis round which the other portion is coiled, and this is the most frequent form of V. There are several other affections of the intestinal tube giving rise to internal strangulation, and similar symptoms to those of V.

The first rule of practice in the treatment of such cases is to abstain from irritating the bowels by purgatives. Nourishment should be given in the fluid and most concentrated form, and in great part by rectal injection. Small pieces of ice should be given to subdue thirst, and opium to alleviate suffering. Belladonna may also be given until the full physiological effect of the drug has been produced, and by this means serious obstruction may be overcome. Mr. Pollock remarks that 'relief in a twist of the sigmoid flexure is just possible without opening the abdomen, provided the long tube be introduced into the distended gut, its contents drawn off, and the twist be reduced by the altered position of the bowel. But no operation for the ultimate relief of the patient will be successful unless the intestines be unloaded first, and the twist then reduced.' Surgical operations may have for their object to relieve the strangulation, or to give an artificial exit to the fæces above it, and colotomy may be practised on either side when the seat of obstruction is in the large intestine. The operation is of a very formidable nature; but is frequently successful, and may prolong life for a considerable time.

Vo'mer (Lat. 'a ploughshare'), a single bone of the Skull (q. v.), so named from its shape. It is placed at the back part of the nasal cavity, and aids in forming the partition separating one nostril from the other. It articulates with the sphenoid and ethmoid bones, and with the two upper maxillary and palate bones. No muscles are attached to it. There is a well-marked groove—the *naso-palatine groove*—in each lateral surface of the bone, which transmits the naso-palatine nerve.

Vom'iting is a very common symptom of disease, but it cannot be considered as a disease *per se*. See Stomach, Diseases of; Indigestion, Sea-Sickness, Sarcina Ventriculi, &c.

Von'del, Joost Van den, perhaps the greatest of Dutch poets, was born November 17, 1587, at Koln, the son of a respectable Dutch couple who had left Antwerp on account of their Mennonite opinions, but before long returned to Holland and settled first in Utrecht and in Amsterdam in 1597. In this latter city V. continued his father's hosiery business, but after his marriage in 1610 left the main management of it in the hands of his wife, and devoted himself to study and the cultivation of his poetic faculty. Though his first poem dates from 1605, he was twenty-five years old before he began to make himself acquainted with Latin, French, and German, as a means of intellectual culture. In 1641 he became a Roman Catholic, was afterwards overtaken by financial ruin, and from 1658 to 1668 was forced to drudge as a bank clerk, but at last obtained a pension from the city. He died at Amsterdam, February 5, 1679. 'In V.,' says Jonckbloet, who is far from a partial critic, 'Dutch poetry reached its zenith.' His principal works took the form of dramas, but the really vital element in all that he wrote was the lyrical. His best pieces are of doubtful success considered as plays, and the worst are redeemed by fine choral passages. His occasional bombast and bathos are more than counterbalanced by a fine play of fancy, a fluency and fiery movement of expression, and masterly management of the verse. His services to the Dutch language in clearing it of barbarisms can hardly be rated too highly. Of his thirty-three plays it is enough to mention *Het Pascha* (1612), on the deliverance of the Israelites from Egypt; *Palamedes* (1625); *Gysbrecht van Amstel* (1638); *Lucifer* (1654); *Jephtha* (1659); *Koning David* (1660); *Adonias, or Fatal Ambition* (*Ramp-zalige Kroonzucht*) (1661). These are all written on the recognised Dutch plan—in Alexandrines, in five acts, and with choral interludes between the acts. The *Lucifer* is of interest as an anticipation in a small degree of Milton's *Paradise Lost*, which it resembles in its covert allusions to contemporary politics. V.'s minor poems are very numerous, and he also translated Sophocles's *Electra*, *Œdipus*, &c., and parts of Horace, Virgil, and Ovid. Lennep edited a complete edition of his works (12 vols. Amst. 1850–69), Grimmelt and Jansen translated his poems (Munich 1873). His life, written by his friend Gerard Brandt in 1683, was printed by Verwijs. See also Bakhuizen van den Brink, *Studiën en Schetsen*; G. Penon, *Hist. en Bibl. Beschouwing van Vondels Heldichten*; Jonckbloet, *Geschiedenis der Nederl. Letterkunde* (vol. ii. pp. 78–164 Gröningen 1874). The tricentenary of his death was celebrated (1879) by the opening of a V. exhibition, containing portraits, &c. of the poet.

Voronej', a government of Russia, surrounded by Tambov, Saratov, the country of the Don Cossacks, Kharkov, Kursk, and Orel. Area, 25,437 sq. miles; pop. (1870) 2,152,096. The surface is in general level, with gentle undulations and chalk hills of no great elevation. The principal river is the Don, with a course from N. to S. of 390 miles. It receives near the town of V. the river V. with its affluent the united Usman and Chava. The principal crops raised are corn, potatoes, beetroot, tobacco, garden produce, and sunflowers, from the seeds of which an excellent oil is procured. In the fine pastures of V. horses and cattle are largely reared. The chief exports are corn and other agricultural produce to Rostov, wool to Kharkov, cattle to St. Petersburg and Kharkov, and horses to most of the governments of Russia.—**V.**, the capital, at the influx of the river V. into the Don, is 310 miles N.N.W. of Rostov by rail. Founded in 1586 as a stronghold against the Tartars, it first became important in the time of Peter I., to whom a monument was raised here in 1860. It has 22 churches, 3 monasteries, extensive tanning industries, and carries on a large trade in corn, sugar, and oil. Pop. (1874) 42,150.

Vor'tex. When any portion of a fluid is set rotating round an axis a V. is produced. Familiar examples are seen in eddies, whirlpools, waterspouts, whirlwinds, and on a larger scale in cyclones and storms generally. The theoretical investigation of V. motion forms a difficult branch of hydrokinetics, and only lately has any distinct progress been effected, mainly by the labours of Stokes, Helmholtz, and Thomson. Helmholtz has proved that if, in a frictionless fluid, a V.-filament, *i.e.*, a column rotating round a central axis, exists, it must either return into itself so as to form a V.-ring, or it must extend through the fluid till it reaches the bounding surface; and also, that where such V.-motion does exist it must always exist, and where it does not exist it never can by physical means be made to exist. Hence the reason why we can form vortices at all is because our fluids are not frictionless; indeed, fluid friction is not only the sufficient but seems to be a necessary cause of V. motion, so that practically V. motion is an inevitable accompaniment of the relative motion of portions of fluid. Of course, because of this friction a V.-filament left to itself speedily disappears, its energy being lost in overcoming the viscosity of the fluid. Another of Helmholtz's interesting theorems is that if a V.-filament is drawn out, it at the same time contracts and rotates faster. This may be effected by moving the filament terminating in two bounding surfaces into a region where the surfaces are further apart. Upon the indestructibility of V. motion Thomson has built his beautiful hypothesis of the V.-atom, which is simply a V.-filament returning into itself after, it may be, several knottings. The simple V.-ring is frequently formed by the smoke emanating from a funnel or a cannon's mouth, and may be very simply produced, as was done first by Tait, by projecting smoke-rings from a hole in one side of a box filled with sal-ammoniac by impacts on the cloth or indiarubber sheeting which forms the opposite side. By such apparatus various curious properties of these V.-rings may be demonstrated, such as their rebounding after collision like elastic solids, their spreading out indefinitely as they approach a plane surface, and the tendency which the foremost of two rings has to expand and slacken speed and permit its contracting and accelerated successor to shoot through it. See Tait's *Recent Advances*, and Stewart and Tait's *Unseen Universe* for a description of V.-rings and their properties, and an explanation of Thomson's V.-Atom Theory. See under HYDRODYNAMICS for a description of Reynolds' interesting experiments. For the mathematics of the subject the reader may consult Clifford's *Kinematic*, or the original papers of Helmholtz and Thomson. The latest application of the V. theory which Thomson has made is to explain the curious anomalies existing in the tides of the English Channel. His results were given in a paper read before the Royal Society of Edinburgh in March 1879.

Vorticell'idæ. See BELL ANIMALCULES.

Vor'tigern, a British prince who flourished in the 5th c. According to Gildas, Bede, Ethelwerd, and the *Old English Chronicle*, he invited Hengist and Horsa to come over and assist him against his enemies the Picts and Scots. Nennius, on the other hand, represents the German chiefs as exiles who came to the island unasked. Whichever form of the story be true, it seems certain that after a short time the new-comers, reinforced by fresh bands of their countrymen, turned against V., and wrested from him the Kentish territory. Nennius is the first to bring 'the beautiful daughter of Hengist' on the scene. He does not, however, name her. This is first done by Geoffrey of Monmouth (12th c.), who in the main follows and expands the version of Nennius. Geoffrey calls her Rowena, or, according to some MSS., Ronwen and Ronwenna; and he is the first to tell the familiar legend of the lady making a low curtsy to V. and saying, as she offered him a cup of wine, 'Lauerd King, wacht heil,' and how the 'devil' made him so enamoured of the lovely pagan that he married her that same night. There is something like unanimity in the chroniclers regarding V.'s character. He was at once tyrannical and lascivious; and monkish indignation (as expressed in the legend of St. Germanus) affirms that he was finally destroyed by fire from heaven. We may at least safely presume that V. came to a violent end, probably in conflict with the heathen adventurers who had established themselves in his dominions.

Vosges, a department in the E. of France, bounded N. by Meurthe-et-Moselle and Meuse, W. by Haute-Marne, S. by Haute-Saône, and E. by Elsass. Area 2269 sq. miles; pop. (1876) 407,082. The surface is covered in the E. by the wooded summits of the V. Mountains, and in the W. consists of fertile undulating plains. It is watered by the Moselle, with its affluents the Moselotte, Vologne, Madon, and Meurthe; the Meuse with the Mouzon and the Vaire; and the Saône with its affluent the Coney. In 1876 there were under cultivation 432,000 acres (12,992 under the vine). In the same year the chief agricultural products were:—wheat, 1,685,060 bushels; oats, 2,750,000 bushels; potatoes, 17,600,000 bushels; wine, 3,234,000 gallons; besides hemp, flax, beetroot, hops, fruits, and tobacco. The industries include silk and wool spinning and weaving, embroidery and lace-making, bleaching and dyeing, and the manufacture of glass, pottery, paper, beet-sugar, beer, leather, and machinery. The capital of the department is Epinal (q. v.).

Vosges Mountains, a range of hills in the E. of France, bounding the valley of the Rhine on the W. and parallel with the Schwarzwald in Baden. They are connected in the N. with the Hardtin Rhenish Bavaria, in the S.W. with the Faucilles, the Côte-d'Or, and the Cevennes, and in the S. they unite with offsets from the Jura. The summits are usually rounded, hence called *ballons*, and are covered with a rich green turf, on which for six months of the year large herds of cattle graze. Their sides are clothed with forests of fir, oak, and beech. Their highest summits range from 3000 to over 4000 feet, culminating in Ballon de Guebriller, 4700 feet above the sea.

Voss, Johann Heinrich, a German poet, translator, and philologist, was born at Sommersdorf in Mecklenburg, 20th February 1751, entered Gottingen in 1772 as a student of theology, but soon renounced this branch of study and gave himself up entirely to philology. He became one of the most celebrated members of the Göttingen Hainbund, a union of young poets of the period who took Klopstock for their model, and when in 1775 he removed to Wansbeck, he from there edited the *Musenalmanach*, the organ of the *Bund*, a periodical which was enriched by some of the early productions of Goethe. In 1778 V. became rector of the school at Ottendorf, and in 1782 of that at Euten. From an early period his literary career was one of continuous labour. He published translations of Homer and Virgil, and engaged in a long and bitter controversy regarding philological questions with Heyne. In the *Almanach* he published several original pieces of poetry, and in 1795 at Königsberg he issued his chief poem, *Luise; ein Ländliches Gedicht* (Eng. trans. by James Cochrane, Edin. 1852), which tells, in hexameter lines, the story of the courtship and marriage of a country clergyman's daughter. This work was received with universal favour, and it is certainly his best original production. In 1802 V. went to Jena, whence he was called in 1805 to the University of Heidelberg. Here he continued his translations. Of these the chief were renderings into German of Horace, Hesiod, and Orpheus, Theocritus, Bion, and Moschus, Tibullus and Aristophanes. His translation of Shakespeare (9 vols. Leip. 1819–30), which he accomplished with the aid of his two sons, was a work of little merit, at least in comparison with Schlegel's magnificent production.

Of his other works in this direction his rendering of the Arabian Nights and (with Höltz) of Shaftesbury's *Philosophical Works* (3 vols. Leip. 1776–79) may be mentioned. The last years of V.'s life were spent in polemical conflict with the representatives of mystico-romantic tendencies. What gave this conflict a certain personal bitterness was the acceptance of Roman Catholicism by his former friend Fritz Stolberg, an act which V. could only regard as a traitorous desertion of the cause of rational thought and progress. V. died at Heidelberg, 30th March 1826. As a writer his good qualities are his vigorous and clear force of expression, and when moralising in a sort of direct didactic vein he is at his best. As a descriptive poet his beau ideal is cosiness, and he expends all his force in describing some comfortable dinner in a snug parlour. But he has not the power of touching commonplace things in an uncommon way; his is no Midas' gift; and a vast proportion of his poetry is in consequence flat, uninteresting, and commonplace. Yet it is somewhat remarkable that what he could not create he could transmute from one language to another. His translations of Homer and Horace are masterpieces: they are as perfect as translations can ever be. He has the merit, moreover, of having made the hexameter one of the recognised metres in German poetry; and we still think of *Luise* with gratitude when we remember that it suggested Goethe's exquisite *Hermann und Dorothea*. Among the more recent editions of V.'s *Sammtliche Werke* are those published at Leipzig (5 vols. 1853) and Berlin (5 vols. 1869). See Paulus, *Lebens und Todeskunden von V.* (Heidelb. 1826) and Herbst's *V.* (2 vols. Leip. 1872–76).

Voss'ius, or **Voss, Gerhard Johann**, an eminent classical scholar of the 17th c. Though born at Heidelberg (1577) he was of Dutch descent, and the greater part of his life was spent in Holland. Educated at Dort and Leyden, he obtained in succession the principalship of the theological college (1614) and the professorate of rhetoric (1621) in the latter of these cities. In 1631 he was called to the chair of history in the Amsterdam gymnasium, where he died, March 27, 1649. V. was distinguished not only by erudition but by philological insight. His *Etymologicum Latinæ Linguæ* (Amst. 1662 and 1695; new ed. by Mazocchi, Naples, 1762–63) is even now a serviceable work, and his *Aristarchus, sive de Arte Grammatica, Lib. VII.* (1635; new ed. by Eckstein and Förtsch, Halle, 1833–34), was greatly in advance of the methods of his time. In his history of the Pelagian controversy (Amst. 1655) he declared in favour of the Arminians. His *Opera Omnia* were edited by his son Isaak (6 vols. Amst. 1695–1701).—**Isaak V.** was the fifth of the six sons of Gerhard V., and was born at Leyden in 1618. In his youth he had the advantage of such professors as Salmasius, Gronovius, and Heinsius, and this was followed up by a wide range of foreign travel in France, England, and Italy. Appointed in 1646 historiographer of the states of Holland, he held the post for only two years, accepting in 1648 an invitation from Christina of Sweden; and for the last eighteen years of his life he lived in England under the patronage of Charles I. He died in London, as canon of Windsor, 21st February 1689. His moral character was quite in harmony with the standard of Whitehall. During service in church he used to amuse himself with Ovid's *Ars Amoris*, and the King wittily remarked that this strange divine would believe anything but the Bible. Most of his works were put in the *Index Expurgatorius*. It is sufficient to mention *De vera Ætate Mundi* (The Hague, 1659), *De Nili Origine* (The Hague, 1666), and *De Septuaginta Interpretibus* (The Hague, 1661), the last a defence of the chronology of the Septuagint.

Voussoirs. See ARCH.

Vow was a solemn promise to dedicate to a deity something of value on the fulfilment of certain conditions, or in the event of receiving from the deity something specially desired, such as deliverance from imminent danger, recovery from sickness, success in an enterprise, &c. Of the same nature as the offerings given in fulfilment of such promises previously made were offerings made purely from gratitude on receiving some mark of the favour of a deity; both were votive gifts. So prevalent was the custom among ancient heathen nations of bringing these *donaria* to their heathen deities, in whose temples they were hung up, that the priests were sometimes obliged to take them down because they were completely concealing the beauty of an altar or pillar. The commonest kind were pictures representing the history of the miraculous cure or deliverance vouchsafed upon the V. of the donor. The temples of Æsculapius were specially rich in these offerings, which, according to Livy, were pay for the cures that he had wrought among the sick. They consisted of images of metal, stone, or clay, as well as models of legs, arms, and other parts of the body which had been cured, and a catalogue of all the miraculous cures effected on his votaries was exposed to view on tablets of brass or marble. This practice was continued by the Christian Church. The churches and shrines of the saints were loaded and disfigured with pictures, images, and models in wood and wax of arms, legs, &c.

The practice also prevailed among the Jews (*cf.* Gen. xxviii. 18–22, xxxi. 13; Job xxii. 27; Ju. xi.; Eccl. v. 4). In the Mosaic law the making of vows was not enjoined; it was expressly left optional (Deut. xxiii. 22, 23; Prov. xx. 25; Eccl. v. 5); but regulations were given for those who chose to make them (Lev. xxvii.). The objects of a V. might be persons, houses, cattle, and land; all of which might be redeemed at a certain fixed rate of value, with the exception of sacrificial animals. But the first-born of man and beast, persons and things dedicated by the ban, and tithes, could not be the object of a V., because they belonged to the Lord by law already. A peculiar V. of abstinence was that of the Nazarite (q. v.).

Vow'el. See LETTERS.

Vul'can (akin to Lat. *fulgere*, 'to glisten,' or to Sansk. *ulkâ*, 'a meteor or firebrand'), in Latin mythology, the god of fire, whose festival fell upon August 23, and whose temple, near which grew a sacred lotus-tree, was said to have been built by Romulus. Roman poets transferred to V. all that the Greek myths related of Hephæstus (q. v.), and thus the two deities became identified.

Vul'can, the name given to the intra-mercurial planet which M. Lescarbault believed he observed crossing the sun's disc on March 26, 1859. In 1856 Leverrier had pointed out that to account for certain irregularities in the motion of Mercury it was necessary to assume the existence of matter between the sun and that planet, and Lescarbault's discovery was hailed as corroborating this theory. The subsequent but unsuccessful endeavours to observe another transit of this body cast grave doubts upon the whole question of existence, and until lately Lescarbault's object was supposed to have been a comet. In 1876, however, Porro and Wolf of Zurich recorded a similar transit; and on July 29, 1878, during the total solar eclipse, which was visible from America, a bright object was observed near the sun by two independent observers, Professor J. C. Watson and Professor Lewis Swift, who are both agreed that what they observed was a planet. Gaillot has compared the position of Watson's planet with the various orbits which Leverrier had assigned as the most probable orbits of Lescarbault's planet, and has shown it to be compatible with one of these. The period of revolution Gaillot fixes at 24·25 days, and gives reasons for believing the inclination of the orbit not to exceed 7°. From recent researches it would appear that earlier observations are on record than those of Lescarbault, notably one by De Vico in July 1837, and one by De Cuppis in October 1839.

Vul'canite, or **Eb'onite**, a form of hardened Caoutchouc (q. v.).

Vul'gate, The, holds the same place as the authentic, authorised translation in the Roman Catholic which the Septuagint holds in the Greek Church. By the beginning of the 5th c. several Latin translations are spoken of, both of the Old and the New Testaments, which in the case of the former were made from the LXX. Of these the best was the one in use in Italy, hence called the *Itala*, a name which is sometimes loosely applied to all the extant remains of the translations made previously to an improved one executed by Jerome (q. v.) in the end of the 4th c. About 382, at Rome, Jerome prepared a new translation of the New Testament, or, to speak more strictly, made a revised edition of the *Itala* New Testament, and revised the Psalter, which he again revised, along with the other books of the Old Testament, at Bethlehem in 384; this latter version receiving the name of the *Psalterium Gallicanum*, as the former that of the *P. Romanum*. But, finally, he made a translation of the Old Testament from the Hebrew. Of his superlative fitness for the work

there can be no doubt. Canon (now Bishop) Lightfoot (*On a Fresh Revision of the New Testament*; 1872) says: 'In the first fifteen centuries of her existence the Western Church produced no biblical scholar who could compare with St. Jerome in competence for so great a task.' And the advantages of his historical position were immense. 'There are extant,' says Mr. T. Graves Law, 'in our European libraries, no more than two or three Greek MSS., and perhaps as many Latin, which reach as far back as St. Jerome's own time. He probably had a dozen where we have one of the oldest class, such as the Vatican Codex, and many of a far earlier date, such as we can never hope to discover. Moreover, he could discriminate between these ancient forms of the text in a way no longer possible to us. We are ignorant of the sources from which our codices are derived, or of the character of their copyists. The caprice or heterodoxy of untrustworthy editors may have had much to do with some of their peculiarities. St. Jerome knew of editions which were thus to be avoided ("prætermitto eos codices quos a Luciano et Hesychio nuncupatos paucorum hominum asserit perversa contentio"), and, on the other hand, he made use of copies which from their known history and antecedents he could trust.' This translation at first met with considerable opposition as an innovation, but by the end of the 5th c. it stood on the same footing as the old Latin translations. Since the 7th c. it has remained the one acknowledged by the Western Church; only the Psalter is according to the *P. Gallicanum* (in the church at Rome the *P. Romanum* retained its authority till about 1566), and some of the apocryphal books—Baruch, Sirach, Wisdom, and 1st and 2d Maccabees—are according to the *Itala*. The Council of Trent (q. v.), on account of the great variety of revised editions of the V., declared (8th April 1546) that the Books of the Old and New Testaments, 'with all their parts as they were wont to be read in the Catholic Church, and as they are found in the ancient V. edition,' are to be held sacred and canonical. At the same time it was resolved to print the text only after the most careful revision, and the researches of Vercellone (*Studi fatti in Roma e mezzi usati per corrigere la Bibbia Volgata*, Roma 1864) and of Ungarelli (*Prælectiones de N. T. et Historia Vulgata*, Romæ 1847) have shown how carefully this was done. The official copy of the authentic V. appeared in 1592, and has ever since remained untouched. Protestant scholars know and admit its merit. Not a few would say with Michaelis that it is *Versionum una omnium præstantissima*. See Dr. Kaulen's *Geschichte der Vulgata* (Mainz, 1868), and Rönsch's *Itala und Vulgata* (2d ed. Marb. 1875).

Vul'ture (*Vultur*), the name given to *Raptorial* birds included in the family *Vulturidæ*, in which there are no 'eyebrows' and a naked head and neck, or at most covered with short feathers. The family *Vulturidæ* includes the vultures of the Old World. The American vultures form a special family, that of the *Cathartidæ*, in which 'eyebrows' are also wanting, and the head and upper part of the neck destitute of feathers. The bill is not markedly of the Raptorial type, the front toes are partially webbed, and the talons blunt. There is no inferior larynx, and a large crop is developed. In both families the wings are long and powerful, and carrion-eating habits prevail. Of the Old-World vultures, a well-known species is the Lammergeyer (q. v.). The Arabian V. (*V. monachus*) is found in Europe, Asia, and N. Africa. Its colour is a dark brown, whilst a hood-like ruff is developed on the neck. The Sociable V. (*Otogyps auricularis*) occurs in S. Africa. Its length is about four feet, and its colour a blackish-brown; the ruff on the neck is black. The Pondicherry V. (*Otogyps calvus*) inhabits India, and is distinguished by a bunch of white feathers springing from the breast. The Griffin V., or Fulvous V. (*Gyps fulvus*), occurs almost universally throughout the Old World. It is one of the largest species, and is of a yellowish-brown above, the ruff being white. The Egyptian or Alpine V. (*Neophron percnopterus*) is found in S. Europe and in Asia. It is also named Pharaoh's Chicken, and the White Crow, from its colour.

Of the New-World vultures, the *Sarcorhamphus gryphus* or Condor (q. v.), the King V. (*S. papa*), the Black V. (*Catharista iota*), and the Turkey or Red-headed Buzzard (*Cathartes aura*), are the best-known examples.

Vyása ('the distributor or arranger'), the traditionary author of the Vedas, the Mahabharata, the Puranas—in fact, of nearly all ancient Sanskrit religious literature. It is evident that in this name is mythically embodied the historical fact that these works at some period underwent a regular and authoritative recension. It merits notice that the Greek name of Homer is capable of being analysed with a similar result.

W.

The twenty-third letter in the English alphabet, found also only in the cognate Teutonic languages, such as German and Dutch. Its name of double *u* expresses its sound; its written character recalls the time when *u* was written as *v*. Like *y*, it is both a consonant and a vowel; in the former case representing *v*, in the latter case *u*. Its consonantal pronunciation in English arises from the proper phonetic value of long *u* = *oo*; and it is similar to, but not identical with, the French *ou*. The Fr. *oui* = 'yes,' as all beginners are with difficulty taught, has a shade of sound different from our 'we.' The combination '*wh*' is anomalous. The aspirate ought to be heard before the '*w*,' except in the case of a following *o*, as 'who,' when the *w* disappears altogether. In this matter the pronunciation of the Scotch is more exact than that of the English. W is also silent when preceding *r*, as 'write.' The vowel use of *w*, which is simply a substitute for *u* in diphthongs, is peculiar to the English language. In Welsh *w* is a vowel taking the place of long *u*. In German *w* is pronounced as our *v*, and Cockneys are said to make a similar confusion. The Franks who came under Gallo-Roman influence changed it into *gu*; *e.g.*, ward becomes 'guard'; wise (Ger. *weise*), 'guise'; war, 'guerre'; William (Ger. *Wilhelm*), 'Guillaume'; warranty, 'guarantee,' &c. In words adopted late into French this philological interchange has ceased, but the sound is preserved in *ou*, as Edouard = Edward. As an abbreviation, W. stands for west.

Waag'en, Gustav Friedrich, a writer on art, was born at Hamburg, 11th February 1794, and educated in Silesia, whither his father, a painter of some note, removed in 1807. As a volunteer he made the campaigns of 1813–14, but subsequently turning to art under the influence of Ludwig Tieck, to whom he was related, he studied at Breslau, Dresden, Heidelberg, and Munich, and after travelling in the Netherlands, published *Ueber Hubert and Johann van Eyck* (Bresl. 1822). He travelled with Schinkel in Italy in 1824, and was appointed director of the picture-gallery of Berlin in 1830. His subsequent life was spent mainly in art tours through Europe, in which he visited France, England, Spain, St. Petersburg, &c., and in writing his *Kunstwerk und Künstler in England und Paris* (3 vols. Berl. 1837–39), *Treasures of Art in Great Britain* (3 vols. Lond. 1854; supplement, 1857), *Kunstwerke und Künstler in Deutschland* (2 vols. 1843–45), *Handbuch der Malerei* (1860), *Handbuch der Deutschen und Niederländischen Malerschulen* (1862), *Die Gemäldesammlung der Kaiserlichen Eremitage zu St. Petersburg* (1864), and *Die Vornehmsten Kunstdenkmäler in Wien* (2 vols. 1866-67). He died at Copenhagen, 15th July 1868. Possessing a scrupulous knowledge of technique and a high-minded devotion to his subject, W. has the honour of having laid a sound basis for the more recent studies in higher criticism. His *Kleine Schriften* were published by A. Wottmann (Stuttg. 1875).

Waal, The (Lat. *Valis* or *Vahalis*), a branch of the Rhine, the main waterway of the larger Rhine vessels, which above Arnhem branches off into the province of Gelderland, and unites near Workum with the Maas. See NETHERLANDS.

Wabash', a river of the United States, rises in the W. of Ohio, flows through Indiana, forming for 120 miles the boundary between Indiana and Illinois, and enters the Ohio at the borders of Kentucky after a course of 550 miles. It is navigable up to La Fayette, a distance of 300 miles, and many steamers ply upon it, coal being plentiful along its banks. The two principal tributaries, the Tippecanoe and White River, are also navigable for steamers. By the W.-and-Erie canal the basin of the Mississippi communicates with that of the St. Lawrence.

Wace, a Norman poet, born in the isle of Jersey about 1120. Besides the various forms of his name, as Vace, Wacce, Waice, Guace, Gasse, and Guasco, some MSS. give him a different name, as Wistace, Huistace, Eustace, and Eustache. In the great majority, however, he figures as 'Maistre Wace;' Huet (17th c.) is the first to call him 'Robert.' He studied at Caen and Paris, and seems to have been employed in the former town in connection with a court of justice. Here, he tells us, he began to write translations, *servantois*, and metrical paraphrases, in which he explained to the people the meaning of the festivals and the merits of the saints whose days they celebrated. To this period, probably, belongs his poem, *C'est comment la Conception Notre Dame fut établie*, first edited by MM. Mancel and Trébutien at Caen in 1842. W.'s *Le Roman du Brut* in the MSS. bears the date 1155. His *Le Roman de Rou*, finished in 1160, was dedicated to Henry II., King of England and Duke of Normandy, who rewarded the minstrel with a canonry in the church of Bayeux. Nothing more is known of W.'s history. That he died in 1174 is only a conjecture. The *Roman du Brut* is mainly a translation into French of Geoffrey of Monmouth's Latin work the *Historia Brittonum*, but W. has enriched the original legend with additions gathered by himself during a visit to Brittany. The poem, which has over 15,000 verses, is marked by clearness, facility, and even precision of style. The first edition, from MSS. in the Paris libraries, was published by M. Le Roux de Lincy at Rouen (2 vols. 1836–38). *Le Roman de Rou* gives in metrical form the history of Normandy from the invasion of Rollo (Fr. *Rou*) to the reign of Henry I. It is divided into four parts not found together in any single MS. The first recites the incursions of the Norsemen; the second and third recount the histories of Rollo himself, of Guillaume Longue-Épée, and of Duke Richard I.; the fourth and by far the largest comes down to the year 1106. The poem contains more than 16,000 verses, partly octosyllabic and partly Alexandrine. The first complete edition was published by Pluquet (2 vols. Rouen 1827; Eng. trans. Lond. 1837). The latest edition by H. Andresen appeared in 1876. W.'s other works are *Chronique ascendante des Ducs de Normandie*, first printed by Pluquet (1825) in the 'Mémoires de la Société des Antiquaries de Caen;' *Vie de Saint Nicolas*, published (1850) by Delius of Bonn; and *Vie de la Vierge Marie, suivie de la Vie de S. Georges* (Tours 1859).

Wad, in Gunnery, is a compressible disc which separates the powder from the projectile. Formerly it was forced home immediately after the powder; in modern ordnance it forms a portion of the Cartridge (q. v.).

Wad, or **Bog Manganese,** is a massive brownish-black mineral composed mainly of the hydrated peroxides of manganese and iron. It is usually mechanically mixed with other oxides and organic acids, and is formed in low situations from the decomposition of manganese minerals.

Wadd'ing, Luke, born at Waterford in Ireland, 16th October 1588, after studying theology at the Lisbon Jesuit Seminary, entered the Franciscan order (1605), and became professor of divinity in the University of Salamanca. As chaplain to an embassy despatched to treat concerning the doctrine of the Immaculate Conception, he came in 1618 to Rome, and settling there, founded the Irish Franciscan College of St. Isidore (1625), acted as papal councillor in the great controversy with the Jansenists, whose tenets he shared at first but presently renounced, and was procurator of his order (1630–34) and vice-commissary (1645–

48). He refused a cardinal's hat, and died at Rome, 18th November 1657, having himself composed the *Annales Ordinis Minorum* (8 vols. Lyon, 1626-40; new ed. 22 vols. Rome, 1731-47) and *Scriptores Ordinis Minorum* (Rome, 1660; new ed. 1806), and edited Calasio's posthumous *Concordantiæ Bibliorum* (4 vols. 1621) and the works of Duns Scotus (12 vols. 1639).

Wadd'ington, George, D.D., son of Rev. George W., vicar of Tuxford, Nottinghamshire, was born 7th September 1793. A brilliant university career at Cambridge was rewarded by a fellowship in Trinity College; and after several years of foreign travel he received the vicarage of Marsham in Yorkshire. In 1840 he was made Dean of Durham, and in the following year Warden of Durham University. He died 20th July 1869. W. was a man of liberal opinions and abundant generosity: his gifts to benevolent institutions both in London and Durham were often princely in their amount. His chief works are *Journal of a Visit to Some Parts of Ethiopia* (Lond. 1822), *A Visit to Greece in 1823 and 1824* (Lond. 1825), *Present Prospects of the Greek or Oriental Church* (Lond. 1829), *History of the Church from the Earliest Ages to the Reformation* (13 vols. Lond. 1835), *History of the Reformation on the Continent* (3 vols. Lond. 1843).

Wadd'ington, Guillaume Henri, a French scholar and statesman, born in Paris in 1826, was the son of a naturalised Englishman who had settled in France as a cotton manufacturer. After four years (1841-45) at Rugby, W. went up to Trinity College, Cambridge, where he closed his career in 1849 by taking a first class in the classical tripos, obtaining a chancellor's medal, and assisting as No. 6 of the university crew in winning the race of the year. It was by his contributions to numismatics and his explorations in Asia Minor that he first attained to celebrity, and in 1865 he was rewarded by a place in the French Academy of Inscriptions. In 1871 he was returned by the department of Aisne to the National Assembly, where he became a supporter of the policy of M. Thiers. In 1876 he was chosen senator for the department of Aisne, along with M. Henri Martin and M. Saint-Vallier, and in the same year he became Minister of Public Instruction. His educational reforms, which sought to give the state full control over the universities, to diminish the influence of the clergy, and to widen the area of primary instruction, were rejected through the opposition of the clerical party. On 16th May he resigned office with the rest of the Simon cabinet, but in December he returned to power as Minister of Foreign Affairs under Dufaure, and as President of the Council formed the new cabinet in the presidential crisis of February 1879. In 1878 he was plenipotentiary of France at the Berlin Congress. Besides his share in the *Voyage Archæologique en Grèce et en Asia Mineure, fait par Ordre du Governement Français pendant les Années 1843 et 1844* (Par. 1847-77), a series of splendid volumes, of which two are devoted to Inscriptions, two to Explanations of Inscriptions, one to Monuments of Antiquity, and one to Architecture, W. is the author of *Edit de Dioclétian, établissant le Maximum dans l'Empire Romain; publié avec de Nouveaux Fragments et un Commentaire* (Par. 1864), *Mélanges de Numismatique et de Philologie* (Par. 1861-67), and *Inscriptions Grecques et Latines de Syrie* (1870).

Wade, Sir Thomas Francis, K.C.B., son of Colonel Thomas W., C.B., was born 1820, entered the army in 1838, and served in China and other parts of the East. He was appointed Interpreter to the garrison at Hong-Kong (1843), Assistant Chinese Secretary (1847), Vice-Consul at Shanghai (1852), and Chinese Secretary at Hong Kong (1855). His intimate knowledge of the Chinese character and language led to his being attached to Lord Elgin's Mission to China (1857-59), and as Chinese Secretary he accompanied his Lordship to Pekin on his Special Mission (1860). In 1862 he became Chinese Secretary and Translator to the British Legation in China, acted as Chargé-d'Affaires at Pekin (1864-65 and 1869-71), and in the last of these years was appointed Envoy Extraordinary, Minister Plenipotentiary, and Chief Superintendent of British trade in China. In November 1875 he was made a K.C.B. for his success in diplomacy and in furthering the interests of British commerce. W. is the author of *Tzü-Erh Chi* (1867), a progressive manual of the Chinese tongue both colloquial and literary.

Wa'ders. See GRALLATORES.

Wad'ham Coll'ege, Oxford, was founded in 1610 by Dorothy, widow of Nicholas Wadham, of Mayfield, Somersetshire, Esq., for a warden, fifteen fellows, fifteen scholars, two chaplains, and two clerks. One of the fellowships was diverted (1857) to the endowment of the chair of experimental philosophy; the scholarships have an annual value of £80, and are tenable for five years; and there are besides ten Hody exhibitions (six Greek, four Hebrew) of £50, two Wright exhibitions (1874) for scholars of Manchester grammar-school, &c. W. C., whose library is rich in rare Spanish books, presents to twelve livings, and in 1878 had 57 undergraduates, 213 members of Convocation, and 367 members on the books.

Wadī (Arab. 'ravine'), in Palestine and Arabia, means either a river or river-valley, or the basin of a torrent. Renan (*Lang. Semit.*) thinks this word was adopted by the Greeks and corrupted into *oasis*. It has passed into the Spanish *guad*, with which many of the Spanish river names begin; thus *W.-l-Kebir* (Arab. 'great river') appears as Guadalquivir, *W.-l-hajarah* ('river of the stones') as Guadalaxara. The ravines of Malta commonly go by the name of *Vyed* or *Wied*, a corrupted form of W.

Wad'set, in Scotch law, a name formerly used to denote a Mortgage (q. v.). See BOND. The word literally means a 'pledge' set or placed over a property. The root is seen in wedding, a 'plighting' or 'pledging' of faith, the betrothal, not (as now) the marriage. Comp. Lat. *vas, vadis*.

Wa'fer is a name given to the small piece of unleavened bread used in the sacrifice of the Mass (q. v.), and called after consecration the Host (q. v.). A bitter controversy arose between the Eastern and Western Churches when the use of unleavened bread was introduced into the latter in the 11th c. At the same time, according to some, the bread was formed in the shape of a penny, to represent the pence for which our Saviour was betrayed. Most likely it was connected with the development of the doctrine of Transubstantiation (q. v.) in the 11th and 12th centuries. At this time every means was adopted to prevent profanation. Thus the communion of children was discontinued. Anxious solicitude was shown in the administration of the cup to prevent spilling, and the use of the W. was probably adopted for the same reason as the cup was finally withheld from the laity altogether.

Wa'fers are thin discs of adhesive matter, formerly much used for securing letters, and still in use for attaching papers to each other, for legal seals, &c. Common flour W. are made by preparing a thin uniform batter of flour and water, pouring the preparation on greased wafer-irons, on which it spreads to a uniform thin sheet, and exposing it to the heat of a clear charcoal fire till it becomes a hard dry thin cake. The cake is allowed to cool, and the W. are then punched out with sharp cutting-punches. They may be coloured to any desired tint by mixing the appropriate dye-stuff with the batter previous to placing it on the wafer-irons. Transparent or gelatine W. are composed of thin sheets of coloured gelatine, to which a small proportion of sugar has been added to facilitate its solution, such cakes being similarly punched into small discs.

Wa'gers. See GAMING, BETTING, LOTTERIES, LAWS REGARDING.

Wa'ges is that share of produce which falls to the labourer employed in the creation of that produce. In ordinary language the term is generally restricted to the remuneration of what in common parlance are called 'workmen,' and certainly this is by far the most important use of the word. Correctly, however, the reward of clerks, professional men, and even capitalists, in so far as the last superintend their own works, are all W., while, on the other hand, the sum paid to most skilled workmen does not entirely consist of W., but part of it must be considered as interest on the original value, and reimbursement for the inevitable depreciation of their tools. The manner in which the produce of human effort is distributed, has been well represented in the following equational form :—

Produce = W. + Rent + interest on capital employed + Taxes.

That part of produce which goes to the labourer forms what is called the W. fund. Of course the rent, the interest, and the taxes may all be spent on W., and thus go to swell that fund, and it is by this constant process that the fund is renewed. In a country like ours, all money that is saved is for the most part spent in W., though in any special case of distribution of pro-

duce, the economic equation given above first obtains, whatever the ultimate destination of the components may be.

It is evident that the remuneration of the labourer in any country must depend (1) on the amount of the W.-fund, (2) on the number of people among whom it is to be divided. This simple and obvious truth has most important consequences. The rate of wages must be determined by the laws of demand and supply, and any attempt to fix an artificial rate by government enactment, must be (*a*) ineffectual or (*b*) hurtful, since while it is possible, by creation of artificial monopolies, &c., unduly to raise the rate of W. in one trade, this can only be effected by depressing it in others. The equation of produce exhibits in a striking manner the exact effect of strikes, locks-out, and generally every combination of employers or workmen. All such combinations aim at assigning a greater or less share of produce as W. In a strike production is stopped. Of course all suffer; but if trade be brisk, it often happens that the employer suffers far more than his workmen. His capital is lying idle; his skill is unexercised; he is paying rent and taxes as formerly. In such a case he quickly surrenders. But if trade be dull, and he cannot find a market for his goods, he is obliged to cut down production. This renders him so far independent of his workmen, and he is able to lower W. His workmen must live. It is now their turn to submit. It would be too much to say that a strike or lock-out is never justifiable. There are various ways in which masters and men may for a time secure to themselves more than their natural share. But that natural share is just the share which is fixed by the laws of demand and supply, and the competition which these generate would act just as forcibly were there never one trade dispute. The equation of produce likewise shows us how far the interests of workmen and employer are the same. They are the same in so far as the *amount* of produce goes; they are different in so far as that produce may be *divided* in very different ratios. In discussing the remuneration of the labourer, a distinction must be drawn between money W. and real W. The real reward of the labourer is not the sum he receives, but what that sum will procure for him. Thus, if the price of corn fall, his real W. are increased to a proportional amount, though the money payment remains the same. W., and the whole class of questions relating to the subject, are discussed in the works of Mill, Fawcett, Jevons, Cairns, W. Thornton, and in Walker's *W. Question and W. Class* (1877).

Wag'ner, Richard, originally **Wilhelm Richard**, an illustrious German composer of 'musical dramas,' and the leader of the 'Music of the Future' school, was born at Leipzig, May 22, 1813. He lost his father, a clerk of police, in infancy, and his education was of a desultory character. Poetry was a passion with him as a boy, and his mind was given up chiefly to verses and play-writing, till an acquaintance with Beethoven's works turned it into a musical channel. In 1833 he wrote an overture for the Gewandhaus concerts, and composed his first opera, *Die Feen*. He was Musical Director of the Magdeburg Theatre in 1836, where he produced *Das Liebesverbot*, an opera alike written and composed by him, which proved a failure. He was subsequently Musical Director at Königsberg and Riga. Impressed with the successes of Meyerbeer, he turned his thoughts to Grand Opera, and began an opera on Bulwer's story of *Rienzi*, in which his avowed aim was to produce grand scenic effects, ensembles, and finales. He looked to Paris as the goal of his artistic ambition, and left Riga on a voyage to that city. The vessel was driven by a storm to the Norwegian coast, where from the winds and waves he caught the inspiration which afterwards burst forth in the *Der fliegende Holländer*. Arrived at Paris, he was befriended by Meyerbeer and Schlesinger, a musical publisher, but his efforts were too fantastic for the taste of the gay city. In great straits, he supported himself by publishing songs and arrangements for the violin and cornet-à-piston, and by writing articles and novelettes in Schlesinger's *Gazette Musicale*, while he matured his two operas. *Rienzi* was produced at Dresden in 1842, with a success which obtained for him the post of Kapellmeister at the Opera House there. *Der fliegende Holländer*, which followed in 1843, marks a new epoch in his artistic history. The existing school of opera, he contended, was false, hollow, and unreal. The drama should be the centre of interest, and music, painting, and architecture only called in as accessories to give complete expression to the poet's thought. The arias of Italian Opera which retarded the action and distracted attention were to be set aside, and instead of recitative he advocated a 'melos,' or endless melody appropriate to each phase of the dramatic interest. For the subject of a drama he preferred a poetical national legend, and henceforward he looked for inspiration to no other source. *Tannhaüser*, the first of his creations from the German myth-world, was produced at Dresden in 1845, and *Lohengrin*, mainly through Liszt's efforts, at Weimar in 1850. Meanwhile the composer had had to leave Dresden on account of his advanced liberal opinions in politics; at Zürich he composed *Tristan und Isolde*, and began his series of works on the *Niebelungenlied*. After ten years of exile he was pardoned by the King of Saxony, but took up his residence in München, where he found King Ludwig of Bavaria an enthusiastic and generous patron. *Tristan und Isolde* was produced in 1865, *Die Meistersinger von Nürnberg* in 1868, *Das Rheingold* in 1869, and *Die Walküre* in 1870. In 1876 the latter two operas, along with *Siegfried* and *Die Götterdämmerung*, his four works on the *Niebelungenlied*, were produced at a theatre specially prepared at Baireuth in presence of the German Emperor and a host of admiring friends. In the same year he composed a March for the American Centennial Exhibition. His latest dramatic effort is *Parcival*. He conducted a series of concerts of his music in 1877 in London, where he had previously appeared at the Philharmonic Concerts of 1855. W., after much uncompromising opposition, has now received a complete recognition of his merits in Germany, to the character of whose people his works and music are most akin. In France they have never been received with favour, and they have not struck deep root in this country, notwithstanding the success of *Tannhauser*, *Lohengrin*, *Der fliegende Hollander*, and more recently of *Rienzi*. He is remarkably inventive in orchestral colouring and scenic effects, and has a high imaginative and poetic genius. There is, however, a flavour of rhapsodical incompleteness in all his efforts, and his true place in the musical world is probably below the isolated height accorded him by extravagant supporters. His views on art may be gathered from his collected writings, *Gesammelte Schriften und Dichtungen* Leip. 1871), including *Oper und Drama* (1852). See Hueffer, *R. W. and the Music of the Future* (Lond. 1874); Glasenapp, *W.'s Leben und Werke* (2 vols. Cass. 1876); Kastner, *W. Katalog* (Offenb. 1878).

Wag'on, or **Wagg'on**, a four-wheeled vehicle for transporting goods or heavy loads, but rarely passengers. Two-wheeled vehicles drawn by oxen were in use among the Egyptians, and most probably the 'wagons' sent by Joseph to bring his father to Egypt (Gen. xlv. 19) were a species of cart or chariot. The invention of the four-wheeled W. has been ascribed to the Phrygians. The ancient *plaustrum*, commonly two-wheeled, had sometimes four wheels, and was employed in carrying loads. The Romans also used the *petorritum*, a four-wheeled carriage, which they borrowed from the Gauls; the name is derived from the Gallic *petor*, 'four,' and *rit*, 'a wheel.' The Old English applied the terms [illegible]*n*, and *crat* or *cræt* (whence our word *cart*), indiscriminately [illegible]elling chariots. In modern England the W. is much used in [illegible]bandry and in transporting merchandise. It is generally drawn by two horses yoked abreast. The fore-wheels are smaller than the hind-wheels, and their axle is swivelled to the body of the W. to facilitate turning. In Scotland the one-horsed cart takes the place of the W. in England. The former economises power, for the horse partly bears and partly drags his load, whereas the animals yoked to the latter expend their force in pulling only, the whole weight of the load being distributed over the four wheels. The brewer's *dray* and railway *lorry* are varieties of the W. Robinson's dumping-W. has a body composed of three separate sections arranged in line and pivoted to the bed of the W. frame. It is employed by contractors on account of the facility and speed with which materials may be 'dumped' or discharged, by disconnecting the sections so that their open ends are tilted downwards.

Wag'on Train, in an army, is the train of wagons used in a campaign for ambulance, ammunition, pontoons, general service, stores, water, &c.

Wag'ram, a small village in lower Austria of about 800 inhabitants, lying on the Russbach, some 10 miles N.E. of Vienna, on the Vienna-Prague railway, was the scene of a great victory gained by Napoleon I. over the Archduke Karl, July 5th and 6th, 1809. The latter lost 25,000 men killed and wounded. The French loss was nearly as great.

Wag'tail (*Motacilla*), a genus of *Insessorial* birds included in the *Dentirostral* section of the order, and in the family *Motacilidæ*. This group in its turn forms a division of the larger family *Sylviadæ* or Warblers (q. v.). Of the wagtails the Red W. (*Motacilla Yarrellii*) is the most familiar species. It is common near every brook, and attains a length of 7 or 8 inches. The male is black on the head, neck, chin, and throat, and white on the sides of the face. White and black markings and patches also occur on the body, and the under parts are grey. The chin and throat become white in winter. The White W. (*M. alba*) has the throat and head alone black, the back and the upper parts generally being light grey. This bird is found in France and S. Europe. The beak of the White W. is broader than that of the pied species. The grey W. (*M. campestris*) is rather locally distributed in England. Its general colour is grey, but there are buff markings on the head and back. The throat and chin are black, and the under parts bright yellow. The average length is 8 inches. The Yellow W. or Ray's W. (*M. sulphurea*) derives its name from the yellow hue of the throat and under parts, the head being olive-coloured. It is common in pastures and meadow-lands.

Wahau'bi (Arab. *Wáhhábî*), a sect of reformed Mohammedans, founded at the commencement of the last century by Abd-ul-Wahhab ('servant of him who gives everything'), the son of a petty chief of the Nejd tribe in the Central Highlands of Arabia. Enlisting the nomad Arabs, from among whom all traces of the pure faith of Islam had disappeared, he raised the standard of revolt against the corruptions and vices of the Turkish court, and in favour of the purity of the Koran. Till his death in 1787 he was the prophet, rather than the general, of the movement, which rapidly spread throughout Arabia. The armies of Bagdad and Constantinople were defeated in several pitched battles, and the holy city of Mecca was captured in 1803. The interference of the Wahaubees with pilgrimage induced the sultan to entrust his most powerful vassal, Mehemet Ali, Pasha of Egypt, with the conduct of the war. Ibrahim Pasha, son of Mehemet Ali, retook Medina in 1812 and Mecca in the following year, following up his victories by the invasion of Nejd, and the burning of the W. capital. But the W. power was not broken; and at the present day it is said to be predominant in the Arabian peninsula, except along the narrow strip of coast that borders the Red Sea. According to Palgrave, the W. state contains 11 provinces and 316 towns or villages, of which the capital is Riad, with a pop. of 40,000. The total pop. is estimated at 1,220,000, including 47,000 fighting men. The W. religion is marked by few peculiarities beyond a fanatical adherence to the original precepts of the Koran and a general spirit of intolerance. Its followers are the Puritans of the East; they eschew fine dresses and the habit of smoking.

In the beginning of the present century the flame spread to India. Syud Ahmed, on his return from a pilgrimage to Mecca in 1[illegible], set himself up as a Calif or Defender of the Faith, and gathered round him at Sitana, on the N.W. frontier near Peshawur, a colony of devoted followers, Pathans and Hindustanis. There he preached a *jihad* or holy war against the infidels; but after some successes against the Sikhs he was defeated and slain by a general of Runjit Singh in 1831. But meanwhile the reform had spread throughout N. India. In the same year his followers, under the name of Feraizees, raised an armed riot in E. Bengal. The apostles whom he had instituted at Patna and other cities taught that the Calif or Imam was not dead but only disappeared; and they were continually sending arms, money, and recruits to the little band which still existed on the N.W. frontier. On the annexation of the Punjaub this band had transferred its fanatical hatred from the Sikh to the Christian infidel. In 1858, 1863, and 1868 regular expeditions were required to curb their inroads. In connection with the second of these occurred the W. state trials at Lahore, which disclosed a deep-rooted conspiracy among British subjects to assist the enemy; and again in 1870 the same story was told in the Patna Court for Lower Bengal. In 1871 the chief justice of Calcutta, who had presided at the Wahaubees' appeal, was assassinated by a Mahommedan glorying in his religious motives. But a stern policy of repression, which inflicted death on none but those who courted martyrdom in the field, or were murderers, stamped out the conspiracy; and it is now believed that the Mohammedan inhabitants of India, though their religion has undoubtedly been purified, are no longer liable to the charge of disloyalty. In the general census, very few returned themselves under the denomination of Wahaubees. See W. G. Palgrave's *Narrative of a Journey through Arabia* (Lond. 1865), and *The Indian Mussulmans*, by W. W. Hunter (Lond. 1872).

Waib'lingen, a town of Würtemberg, on the Rems, 15 miles E.N.E. of Stuttgart by rail, has a fine Gothic church (1459–88), two schools, a new Rathhaus, and manufactures of silk, cloth, leather, &c. Pop. (1875) 4128. From this town, or (according to Raumer) from another fortress of the same name on the Kocher, the Hohenstaufens assumed the appellation Waiblinger, corrupted by Italians into Ghibellini.

Waifs, in English law, are stolen goods that have been 'waived' or dropped by the thief when pursued. The name has been figuratively given to all unfortunates who have slipped their social moorings and drift about in helpless misery.

Wain'scot, a term now applied to figured oak wood used as wall linings and for other facings, and more particularly to any imitation of such oak in paint. It was originally applied to panelled linings generally, such as formerly were used as dados of apartments.

Waist, of a ship, the part of the upper deck between the quarterdeck and the forecastle.

Waits (akin to O. H. Ger. *wahta*), a term originally applied to *watchmen*; next, as these sang in rude rhymes the passing hours of night, to hired serenaders; and lastly to such musicians as go about playing and singing Christmas Carols (q. v.).

Wait'zen (Mag. *Vác*), a town of Hungary, comitat of Pestn, on the Danube, 23 miles N. of Pesth by rail. It is an episcopal see, has a cathedral built in 1761–77 on the model of St. Peter's at Rome, four other Catholic churches and one Protestant, deaf and dumb institute, bishop's palace, with classical and mediæval art treasures, and a prison (1857) in Gothic style. W. carries on an important trade in wine and cattle. Pop. (1870) 12,894. The town has been the scene of various battles between Hungarians and Turks, Hungarians and Austrians, and Hungarians and Russians, the most celebrated of which perhaps is that of 10th April 1849.

Wake. See VIGIL and FAIRS.

Wake'field, an ancient market-town in the W. Riding of Yorkshire, England, on the Calder, 9 miles S. of Leeds by the Great Northern Railway. It has five main streets, one of which slopes down towards the left bank of the Calder. The parish church of All Saints, in the Perpendicular style, was consecrated in 1329, but with the exception of the spire was rebuilt in the last century. It was 'restored' under the direction of Sir G. G. Scott (1857–74) at a cost of £20,000, including the spire, which now measures 237 feet in height. The other Episcopal churches are St. John's (1795), Holy Trinity, St. Andrew's, St. Michael's (1858), St. Mary's (1874), and Christ's (1875). On the bridge across the Calder is a very fine chapel, 'restored' in 1847. The public buildings of W. include a corn-exchange (1837), the town-hall, a court-house, a church institute, a mechanics institute, assembly-rooms, a grammar-school, at which Dr. Radcliffe and Bentley the critic were educated, a fine-art institute (1868), the W. Riding Pauper Lunatic Asylum, the W. Riding Prison, and a union workhouse. A magnificent railway station was opened in 1867; a new market, covering 2665 sq. yards, and a new hospital, costing £14,000, were commenced in 1876. The main industry of W. has long been the manufacture of woollens, worsteds, and hosiery, but this department of trade has of late years passed largely to other towns in the neighbourhood, and W. is now more important as a great corn-mart. There are extensive collieries, corn and flour mills, breweries, chemical works, foundries, and engineering works. The town has excellent communication with the neighbourhood by railways and canals. W. is practically the chief town of the W. Riding, and is the seat of the Probate and County court, the headquarters of the Riding constabulary, and contains the offices of the clerk of the peace and the Riding solicitor. Pop. (1871) 28,069.

Wakefield, Gilbert, a classical scholar and theologian, was born February 22, 1756, in the parsonage at St. Nicholas

of Nottingham, and in 1776 became a Fellow of Jesus College, Cambridge. After holding two curacies in the Church of England, he obtained (1779) a classical tutorship in a dissenting academy, and in 1786 he formally withdrew from his connection with the Established Church. For two years (1799-1801) he was imprisoned in Dorchester jail for a seditious libel contained in his *Reply to some Parts of the Bishop of Llandaff's Address to the People of Great Britain* (Lond. 1798), and a few months after his release he died, September 9, 1801. W. attacked the Church of England with more than the bitterness of a renegade, and keenly impugned the main docrines of Christianity and the expediency of public worship; but 'in domestic life he was,' according to H. C. Robinson, 'a most gentle creature, with the pale complexion and mild features of a saint.' As a critic he was rash, but suggestive and copious, and was considered by Dr. Parr 'as one of the best scholars produced by his own country in his own age.' Besides editions of Horace (1794), Bion and Moschus (1795), Virgil (1796), Lucretius (1796-97), a *Translation of the New Testament* (1791), and numerous pamphlets, W. was the author of *Poemata* (1776), *An Essay on Inspiration* (1784), *Silva Critica*, consisting of notes to the Scriptures from the secular classics (1789-95), and *Evidences of Christianity*. He wrote his own *Memoirs* (Lond. 1792; new ed. by Ruth and Wainewright, 1804), and his *Correspondence with Charles James Fox* was published in 1813.

Walcher'en, an island of the province of Zeeland, Netherlands, between the two mouths of the Scheldt. Area, 52,100 acres; pop. 43,171. It is a low, flat island, protected against the sea by thick dykes, and on one side by sand-hills. The island has, nevertheless, been subjected to several disastrous inundations. Fine wheat and potatoes are raised, and excellent cattle are reared on the rich pasture meadows. Fishing is also prosecuted. Saw-mills, tanneries, breweries, and shipbuilding yards afford employment to the inhabitants of its 18 villages and the towns Middelburg, Veere, and Flushing. *W. Expedition* was a disastrous scheme devised in Britain during the Napoleonic wars with the view of creating a diversion in favour of our Continental allies. After many delays, nearly 50,000 men, under the command of Lord Chatham, sailed for W. on the 28th July 1809. Instead of advancing on Antwerp the general devoted more than a month to the reduction of Flushing. Meanwhile, French reinforcements had poured into Antwerp, whilst the British army was decimated by sickness. The troops, with the exception of 15,000, were therefore withdrawn. This garrison, however, continued a prey to fever, and had also to return to England without further achievements.

Wal'deck (*W.-Pyrmont*), a sovereign principality in the W.N.W. of Germany, comprises the former county of W., girt by the Prussian provinces of Westfalen and Hessen-Nassau, and that of Pyrmont lying apart between Lippe, Hannover, Braunschweig, and Westfalen. Area, 438 sq. miles; pop. (1875) 54,711. W. is among the highest districts between the Rhine and Weser, the greatest elevations being the Hegekopf (2750 feet), near Stryck, the Ettelsberg (2703), and Pön (2519). The country, picturesquely diversified with vale and upland, plain and forest, is watered by the Weser, Eder, Werbe, Itter, Aar, Diemel, and Twiste. At Niederwildung are chalybeate springs, and at Pyrmont are famous steel and iron springs. The chief crops are rye, oats, and potatoes. The woods cover 105,142 acres; and in 1873 there were 5699 horses, 19,714 cattle, 59,859 sheep, 15,289 swine, 7707 goats, and 3073 bee-hives. Formerly of importance, the mining industry produced in 1876 iron-ore to the value of £743, as well as some manganese, &c. The principal export is the mineral water of Wildung (316,323 bottles in 1876), which is sent as far as Japan and China. The princely house of W. dates from the 12th c., and till the end of the 14th possessed Swalenberg and Sternberg. George Victor (born 1831) negotiated a 'Treaty of Accession' in 1867, by which he transmitted the administration to Prussia, himself retaining merely nominal power. The treaty was confirmed in 1878. See Kurtze, *Geschichte des Fürstenthums W.* (Arol. 1850), and *Beitrage* (*ib.* 1864 *et seq.*).

Walden'ses, or **Walden'sians** (*Valdenses, Valesi, Vaudois*, the last not to be confounded with *Vaudois*, equivalent to inhabitants of the canton Vaud or Waadt in Switzerland), an interesting community of Reformers before the Reformation which still maintains its existence as a separate Christian church. Its originator was Peter Waldo (Valdez or Waldus), a citizen of Lyon, who having procured a translation of parts of the Bible from two young priests, sought to frame his life after the example of the Apostles, sold his goods and gave to the poor, and began to preach the doctrine which he practised. By and by men of like mind joined themselves to him, and they became known as the *Poor Men of Lyon* (Pauperes de Lugduno). Jean de Belle Main, archbishop of Lyon, ordered them to refrain from preaching, and at the Council of Verona 1184 they were threatened with excommunication by Pope Lucius III., along with the Catharians and the followers of Arnold of Buscia; but though they had no desire to break with the Church they held on their way, and at length in 1215 at the Lateran Council the papal threat was put in execution. Notwithstanding, they continued to spread, and by the end of the 13th c. they were to be found in the north of France, in Italy, Spain, and Germany, being especially numerous in Piedmont and Lombardy. As the action of the Church grew more hostile their creed took a more heretical form. The denial of purgatory and opposition to the clerical monopoly of the right to preach were its most striking features, both due, it is to be noted, to the *moral* rather than the *doctrinal* character of the movement. At length the extreme members began to regard the Church of Rome as the church of the Evil One, and themselves as the real Church of Christ. In 1477 Sixtus IV. preached a crusade against them in their headquarters in Savoy, in 1541 François I. ordered them to be rooted out in Piedmont, and in 1560 the Duke of Savoy led against them an army of 7000 men. A new persecution was commenced in 1655 by Charles Immanuel, and the 'bones of the slaughtered saints were scattered on the Alpine mountains cold;' but the voice of Protestant Europe, and most effectually the voice of the most imperative Protestant Cromwell, was raised in their defence, and a convention was concluded in their favour. On the revocation of the Edict of Nantes Louis XIV. compelled them either to emigrate or conform; but in 1689, when William of Orange became King of England, a large body ventured to return to Savoy. Straightway attacked by the French and the Piedmontese, they were able to keep their enemies at bay till the Piedmontese, having broken with the French, agreed to grant them an amnesty. But it was not till 1848 that they received from the King of Sardinia the same civil and religious rights as his Roman Catholic subjects. At the present time the W. inhabit the Val Martino, the Val Angrona, and the Val Lucerna, which lie about 27 miles S.W. of Turin, and are traversed by the headwaters of the Po. They number about 25,000, have 40 congregations, and maintain, according to the report of 1875-76, 16 mission stations. The liberty of preaching, which was formerly enjoyed by both men and women, was placed under restrictions by the new constitution of 1839. See Sir Samuel Morland (Cromwell's envoy), *History of the Evangelical Churches in the Valleys of Piedmont* (Lond. 1658); Faber, *Theology of the Ancient Vallenses* (Lond. 1838); Weiss, *Die Kirchenverfassung der Waldenser* (Zür. 1844); Henderson, *Observations on the Vaudois Church* (Lond. 1844); Baird, *History of the W.* (Lond. 1846); Monastier, *Histoire de l'Église Vaudoise* (Toul. 1847; Eng. trans. Lond. 1848); Bender, *Geschichte der Waldenser* (Ulm 1850); Muston, *L'Israel des Alpes* (4 vols. Par. 1851; Eng. trans. new ed. 1863); Dieckhoff, *Die Waldenser im Mittelalter* (Gött. 1851); Williams, *The Waldensian Church* (Lond. 1854); Herzog, *Die romanischen Waldenser* (Halle 1853); Lechler, *Studien und Kritiken* (1855); Wylie, *Valleys of the W.* (Lond. 1858); Palacky, *Die Beziehungen der Waldenser zu der ehemal, Sekte in Böhmen* (Prague, 1869); Melia, *Origin of the W.* (Lond. 1870); Lechler, *Joh. von Wiclif* (Leip. 1873, vol. i.); and Preger, *Beiträge zur Geschichte der Waldenser* (Mün. 1875).

Wales. See ENGLAND AND WALES.

Wales, Albert Edward, Prince of, eldest son of Her Majesty Queen Victoria, and heir-apparent to the British throne, was born at Buckingham Palace, 9th November 1841. After a careful education under four private tutors, he spent a session at the University of Edinburgh, a year at Oxford, and another at Cambridge, and in 1860 made a tour through Canada and the United States, which over, he joined the Curragh Camp, having been gazetted colonel in 1858. In 1862 he travelled with Dean

Stanley in the East, and on 10th March 1863 he married the Princess Alexandra (born 1st December 1844), eldest daughter of the reigning King of Denmark, Christian IX., by whom he has issue, two sons and three daughters, the eldest, Prince Albert Edward Victor Christian (born 8th January 1864). His recovery from a six weeks' attack of typhoid fever was celebrated by a Thanksgiving Service in St. Paul's, attended by 13,000 persons, 27th February 1872; and that loyalty is not confined to England was abundantly proved during the Prince's visit to India (October 1875–May 1876), whose events are chronicled in Dr. Russell's *Tour of the P. of W. in India* (Lond. 1877). In 1878 he was re-elected to the Grand-Mastership of the Freemasons, a dignity conferred three years before, and in October of the same year he received an address bearing 1000 signatures, 'thanking him for his great exertions in connection with the Paris Exhibition.' For his various titles see PRINCE OF WALES.

Wales, New South. See NEW SOUTH WALES.

Wal'fisch Bay is situated on the S.W. coast of Africa, in 22° 50′ S. lat. It possesses safe anchorage, but is without fresh water, and its shores are barren and desolate in the extreme. Fish are very abundant, and it was formerly a favourite whaling-ground, whence its name. Valuable deposits of copper and lead exist some distance inland, but are not yet worked. The climate of W. B. is almost rainless, and is fairly healthy except in the hot months, when low fever prevails. In 1878 the coast-line between the Cunene and Orange rivers, a distance of 720 miles, was annexed to Cape Colony, the British flag being hoisted at W. B. The strip of land thus taken possession of is from 13 to 18 miles broad.

Walhall'a. See VALHALLA.

Walk'er, Frederick, an English artist, was born in Marylebone, 24th May 1840, studied at the British Museum and at 'Leigh's,' and by the time he entered the Academy (1858) was earning a livelihood by designing wood-engravings. His beautiful drawings in *Once a Week* brought him into notice. Engaged by Thackeray to help him out with his illustrations for the novels, he was the 'F. W.' who gave to the crude designs of the humourist their charm of spirit, finish, and grace. He drew much for the Messrs. Dalziel Brothers, but with Miss Thackeray's *Village on the Cliff* ended his work for the engraver. He now devoted himself to painting, both in oil and water-colours. In the first his works were 'The Lost Path' (1863), 'Bathers' (1867), 'Vagrants' and 'In the Glen, Rathfarnham Park' (1868), 'The Old Gate' (1869), 'The Plough' (1870), 'At the Bar' (1871), and 'The Harbour of Refuge' (1872). His water-colours comprise 'Spring' (1863), 'The Bouquet' (1866), 'Fisherman and Boy' (1867), 'Streams in Inverness-shire' (1868), 'Wayfarers' (1870), 'Girl at a Stile' and 'The Housewife' (1871), 'The Escape' (1872), 'The Village' (1873), 'The Rainbow' (1874), and 'Fishmonger's Shop' (1875). Some of these are technical masterpieces, and all are alive with sentiment and meaning. The drawing is well-nigh perfect, the colour clear and delicate, and the prevailing tone that of the tenderest pathos, tinged with humour. In his love of beauty and in graceful inventiveness W. evinced the deep influence of the early study of the antique. He was made an associate of the Old Water-Colour Society in 1863, and a full member in 1866, and was elected an associate of the Royal Academy in 1871. He died at St. Fillan's, Perthshire, 4th June 1875. An exhibition of 150 of his works took place in 1876.

Walk'er, George, D.D., a clergyman famous in Irish history, was born about 1650 in county Tyrone, and educated at the University of Glasgow. When Londonderry was besieged by James and deserted by its governor, W. organised its defence, and by his eloquence and heroism succeeded in repulsing the assailants till the siege was raised. He received the thanks of the House of Commons, the degree of D.D. from Oxford, and the bishopric of Derry with £5000 from King William. His *True Account of the Siege of Londonderry* (Lond. 1689, Edin. 1698) was followed by *A Vindication* (Lond. 1689), and in the same year he published *A Sermon; being an Encouragement of Protestants.* W. was killed at the battle of the Boyne, July 1, 1690. In 1828 the city he had served erected a monument to his memory.

Walking-Leaf. See LEAF INSECT.

Walking-Stick Insects (*Phasmidæ*), a peculiar family of *Orthopterous* insects, so named from the resemblance of their bodies to dried twigs. They present good examples of the *Mimicry* (q. v.) of other objects by animal forms. The body is long and linear, and the wings are short and rudimentary. *Phasma* has antennæ nearly as long as the body, and there are wings in both sexes. *Phasma gigas* of the E. Indies exemplifies the group, and *Phasma guttatum* is a Bornean species.

Walking-Sticks are made from the branches of almost every conceivable tree and shrub; but the numerous varieties of cane and bamboo are the most suitable from their size and form, and therefore 'cane' and 'bamboo' W.-S. are to a large extent synonymous. The Malacca cane and the Penang Lawyer are the most highly prized. (See CANE and BAMBOO.) The hard and fancy woods are also largely utilised for the manufacture of W.-S., the better varieties being often ivory-handled and mounted in gold or silver ferrules. Sword-blades, stilettos, knives, cork-screws, tobacco-pipes, and like objects, are often fitted into the hollow upper end of W.-S.

Wall'ace, Sir William, the champion of Scottish independence, and, in popular belief, the noblest incarnation of patriotism recorded in history, was born in the second half of the 13th c. The immortal fable of Blind Harry (q. v.) forms part of the national creed, and is so universally known that it need not here be repeated in detail. To what family the hero belonged we can only conjecture from the name he bore; but of his antecedents previous to the revolt against the English domination in 1296–97 nothing is really known. It is not improbable, however, that the tradition which connects him with the contemporary Wallaces of Elderslie is correct. Its universality is in its favour. But no evidence of adequate antiquity exists to prove it. The oldest authorities are silent on the point. Wyntoun merely says, 'hys fadyre wes a manly knycht' (Bk. viii. chap. xiii.), and the genuine Fordun (see Skene's edition in the *Historians of Scotland*, vol. i. p. 328) is not more definite, though more detailed. It is not till we reach the distant age of Blind Harry—nearly two centuries later—that we learn anything of his family, or are furnished with any biography of the hero. Setting aside the prodigious fictions with which the rude minstrel envelops the youth of W., the first genuine glimpse we obtain of the patriot is in Lanark in the spring of 1297, when he surprised and slew the English governor, Hesilrig. This incident does not rest on the comparatively late authority of the Scottish chroniclers, though the testimony of Wyntoun in particular is not to be lightly esteemed. In the *Scalachronica* (p. 124) Sir Thomas de Grey, a Northumbrian knight, tells how his father was in garrison at Lanark in May 1297, when W. fell upon the English quarters, killed the governor, and set fire to the place. As Grey's father was severely wounded and left for dead in the street, he could scarcely be mistaken in the fact. This affray was probably the beginning of the national insurrection against the rule of the foreigner—a rule which the orders sent by Edward to Cressingham (see Hemingford and the *Fœdera*) show to have been singularly harsh and oppressive. Fordun's statement is: 'Ex eo igitur tempore congregati sunt ad eum omnes, qui erant in amaro animo, et oppressi pondere servitutis sub intolerabili principatu Anglicanæ dominationis, et factus est eorum dux.' From a guerilla chief, a captain of patriotic Adullamites, he rose to be a national leader: without almost any help from the nobles, he drove the English garrisons out of the larger part of Scotland, won a great battle at Stirling (August 1297) over Warenne Earl of Surrey, devastated the North of England in the following winter, and in July 1298 was utterly crushed at Falkirk by the overwhelming force of Edward I. He then vanishes from our sight, only to reappear at his capture near Glasgow and execution in London seven years afterwards (23d August 1305). This is substantially his whole biography. His public career embraces a period of no less than fifteen months; his private history is a blank.

The extraordinary fable that has superseded this meagre record, and that has infected with an absurd credulity almost the whole series of Scottish historians, is chiefly, though not wholly, the product of Blind Harry's barbarous imagination. Long before the minstrel was born, patriotic pride had been generously at work, after its vaunting fashion, to clothe the hero with every attribute of majesty and to celebrate his prowess with the splendid exaggerations of romance. Wyntoun tells us (Bk. viii. chap. 15) that, before even his time, 'gret gestis' had been made

about W., while the continuator and interpolator of Fordun exhausts his admiration and his Latin in the effort to describe the physique of the national champion: 'Erat enim statura procerus, corpore giganteus, facie serenus, vultu jocundus, humeris latus, ossibus grossus, ventre congruus, lateribus protelus, aspectu gratus sed visu ferus, renibus amplus, brachiis et cruribus vigorosus, pugil acerrimus, et omnibus artubus fortissimus et compactus.' It is not wonderful that with such grotesque enthusiasm to encourage him, Blind Harry should feel himself at liberty to conduct his hero through a brilliant succession of impossible exploits. That everything is fiction we do not require to believe. Blind Harry's poem teems with evidences of his topographical knowledge, but nothing is conceived and nothing is recorded in a historic spirit. The moment he passes beyond the narrow limit of ascertained facts, we are lost in an imbroglio of incredibilities, and even the facts themselves are perverted and distorted in the most ridiculous manner. The story of W.'s youth—which almost every Scot feels it a religious duty to believe—is utterly impossible. There were no English then in Scotland. To describe them, moreover, as the 'auld mortal faes' of that country is a ludicrous anachronism, yet it is assigned as one of the motives of W.'s implacable hatred of the Southrons. The battle of Stirling Bridge is a model of extravagant absurdity, but in order to realise the profundity of the minstrel's fiction it is necessary to carefully study the eighth canto of his poem. The contemporary English chronicler Hemingford states that W. burnt and devastated *totam Northumbriam usque Novum castrum.* But this petty retaliation does not satisfy the ambitious patriotism of the bard. The victorious Scots are carried south through Durham, York, and the midland counties as far as St. Albans. Edward, the first soldier in Europe, fleeing before them, and followed apparently by all the burgesses and peasantry in the land. Nor is this all. W. threatens to besiege the metropolis itself if the English king will not come out and fight him. Every one trembles at the approach of this new Goliath. No one has the courage to approach him and sue for peace, till the queen herself declares that she will undertake the perilous mission, whereupon Blind Harry's audacity culminates in the declaration that it was rumoured the queen was in love with the patriot chief. The result of the interview convinces her that the virtue of W. is as invincible as his prowess. To her prayers, her arguments, her blandishments he sternly turns a deaf ear; and she returns to London in dejection. By her advice Edward makes peace with the conqueror, and solemnly abjures every right of sovereignty over Scotland. How deeply this wild delusion, known as the History of W., took possession of the Scottish mind may be judged from the fact that a man like Dr. Jamieson (see the new edition of his *Blind Harry*, by Maurice Ogle, Glasgow, 1869) actually wrote to Mr. Henry Ellis of the British Museum, to ascertain if there was anything in the MSS. of that library to corroborate the story of the interview between the English queen and W. Few Scotchmen quite distinctly apprehend that the whole groundwork and conception of the minstrel's poem is fantastically erroneous, that he knew really nothing of the character or duration of the struggle, and that the vast majority of the incidents are the manifest offspring of unbounded credulity. The work in short is valueless for biographical purposes, a fact that need not be regretted, least of all by the countrymen of W. For there is much in *Blind Harry* to lessen our admiration of his hero. The author was familiar with the romances of chivalry to which he frequently alludes, and he borrows from their pages some of their worst peculiarities. He is more solicitous to present the patriot as unequalled in prowess than wise in council or humane in war; and while he cannot quite overlook the national struggle or forget that W. had a policy and fought for a purpose, his supreme delight is to turn aside from the conflict of hosts to the bloody details of private encounters, in which the sword of the invincible knight makes havoc of squadrons and inspires universal dismay. Nowhere does a gleam of civic virtue or sovereign statesmanship lighten the path of the warrior. Yet the only certain occurrence in his public career which in any way illustrates his public aims is his recently discovered letter to the corporations of Lübeck and Hamburg, inviting the merchants of these cities to resume their commercial intercourse with Scotland, which had apparently ceased during the confusions that followed the English Conquest.

The truth is, that while *Blind Harry* tells us nothing of W. that is worthy of belief, it throws a powerful light on the age of the minstrel himself. In its fierce and passionate verse we see the pernicious result of the desperate attempts of the English kings to overthrow the liberties of a proud and obdurate people. An intense hatred of England was the inevitable result of a hundred years of bloody and unprofitable strife. The animosities of the poem are those of the 15th and not of the 13th c. Blind Harry's vision of the Past is discoloured by the smoke and flame of the intervening period, when the slopes of the Cheviots continually re-echoed the shouts of a 'Douglas' or a 'Percy.' Yet though Scotchmen may be no longer willing or able to say with Burns that *Blind Harry* has poured a Scottish prejudice into their veins 'which will boil along there till the floodgates of life shut in eternal rest,' they may without challenge cherish a proud remembrance of the man who saw or felt that there was the making of a distinct and precious nationality in his countrymen, who refused to have it obliterated, fought with a heroic energy for its development, and breathed into the new community the breath of a sterner and more fervid life. See the older authors, Wyntoun, Fordun, and Blind Harry, the modern histories of Tytler and Hill Burton, the W. Papers, Carrick's *Life of Sir William W.*, and the slight but sensible paper of the Marquess of Bute on *Sir William W.* (Paisley 1876).

Wall'ace, Alfred Russell, an eminent English naturalist, was born, 8th January 1822, at Usk, in Monmouthshire, and received most of his education at Christ's Hospital, Hertford. At an early period he turned his attention to natural science. He has made two remarkable series of explorations—the first along with Mr. Bates from 1848 to 1852 in the valley of the Amazon, and the second independently from 1854 to 1862 in the E. Indian Archipelago. He has formulated a theory which in all its main features coincides with the natural selection of Mr. Darwin; and his observations and researches have done as much as those of any man living to assist in working out the problems associated with the theory. The natural history collections made during his travels were unusually rich. Most of those from the Amazon, as well as many of his manuscripts, were lost in the passage home; but he succeeded in bringing to England from the E. Indies about 125,000 specimens, including 100,000 insects and 8000 birds. His name has been given to a channel running between Lombok and Bali, which he has indicated as marking out the boundary between the Asiatic and the Australian region. In recent years W. has avowed himself an advocate of spiritualism convinced against his will. The following are his principal works—*Travels in the Amazon and Rio Negro* (Lond. 1853; new ed. 1870); *Palm Trees of the Amazon* (Lond. 1853); *The Malay Archipelago* (2 vols. Lond. 1869); *Contributions to the Theory of Natural Selection* (Lond. 1870), a collection of essays and papers from scientific periodicals; *Miracles and Modern Spiritualism* (Lond. 1875), a reprint of papers contributed to the *Fortnightly Review* (1874); *On the Geographical Distribution of Animals* (Lond. 1876), an elaborate survey of all ascertained facts on the subject, enriched by the results of much original research; and *Tropical Nature* (Lond. 1878), on the colours of natural objects, sexual selection, &c.

Wall'ace, William Vincent, an English composer, was born at Waterford, of Scotch parentage, June 1, 1814. His father, a regimental bandmaster, gave him his first lessons, and at an early age he could play most military instruments, besides becoming a proficient on the violin and pianoforte. At the age of fifteen he went to Dublin, where he became director of the Philharmonic Society. His health failing, he made a voyage to Australia, and after having recruited it he undertook a professional tour through the Antipodes, Oceania, India, S. America, and the United States, creating a furore in his dual capacity of composer and performer. He was director of music at the Italian Theatre, Mexico, in 1841-42. In 1846 he produced *Maritana* in London and Vienna, an opera which ran for 100 nights, and now shares with Balfe's *Bohemian Girl* the highest popularity of any native lyrical drama. *Matilda of Hungary* was also produced in this year at the same cities, and was followed by the *Maid of Zurich*, *Gulnare*, and *Olga*. He was commissioned to compose a work for the Grand Opera in Paris in 1849, but the temporary failing of his eyesight prevented his accepting this honour. His *Lurline*, produced in London in

1860, is one of his best operas, the score being a work of genius. *The Amber Witch* (1861), *Love's Triumph* (1862), and the *Desert Flower* (1863), were his last operatic efforts. He died at the Château de Bagen, in the Haute Garonne, France, October 12, 1865, leaving, in addition to his operas, a great number of nocturnes, waltzes, studies, songs, and compositions for the pianoforte. W. had a high intelligence, a fine flow of melody, a sound orchestral knowledge, was a man of culture and an admirable linguist. See his Memoirs in French by Pougin (Par. 1866).

Wall'ace, Robert, D.D., a Scottish theologian and journalist, was born in the parish of St. Andrews, Fifeshire, June 24, 1831, educated at Geddes Institution, Culross, the High School of Edinburgh; studied for the Church at the University of St. Andrews, where he graduated M.A. in 1853, and at Edinburgh. He was chosen minister of Newton-upon-Ayr (1857), translated to Trinity College Church, Edinburgh (1860), thence to Old Greyfriars' Church in the same city (1868), and appointed Professor of Church History in the University of Edinburgh (1872). He received from the University of Glasgow the degree of D.D. in 1869. At first intensely anxious to do his duty by the traditional theology of Scotland, W. seems to have been led, step by step, to abandon the assertion of its cardinal positions, until his intellectual attitude assumed the aspect of an apparently unqualified Rationalism. Yet so long as he found it possible to harmonise himself with his theological environments, he had both freedom and followers within the National Communion. His brilliant talent for debate, his humour, self-possession, force of intellect, and fulness of knowledge, made him popular even with his opponents, and many Churchmen felt an emotion of genuine grief when in 1876 he formally withdrew from the clerical profession. Since then W. has held the office of editor of the *Scotsman*, in succession to the late Alexander Russel.

Walla'chia. See RUMANIA.

Wall'enstein, properly **Waldstein, Albrecht Eusebius Wenzel von,** was born of noble but impoverished parents at Hermanic in Bohemia, 14th September 1583. An orphan at the age of twelve, he was entrusted to the care of the Bohemian Brethren at Kaschumberg, but four years later he joined the Jesuits at Olmütz. In 1559-60 he was at the Lutheran University of Altorf, and thereafter we find him studying in Padua, and travelling in Italy, Germany, and the Netherlands. He gained large estates by marriage with a rich widow, who died in 1614. With his own troops W. raised the siege of Gradisca by the Venetians, and was rewarded with the title of Graf, and the command of a regiment in Moravia. His marriage in 1617 to a relative of Graf Eggenberg, and his conduct during the Bohemian revolution, procured him the favour of the Emperor. He profited immensely in the confiscations after the rising, securing Friedland and Reichenberg in 1621 for 150,000 florins, and in 1622-24 estates to the value of 7,290,000 florins. Part of the money was covered by his own expenses, and part he paid with debased coin. He was made a Prince of the Empire in 1623, and Duke of Friedland in 1624. The preparations of Christian IV. forced Ferdinand in 1625 to accept W.'s proposal to levy 20,000 men at his own expense. Appointed commander-in-chief on the 25th July, W. raised a much larger force, occupied the diocese of Halberstadt in the autumn, and on the 25th April 1626 completely defeated Mansfeld at Dessau. Entering Schlesien in June 1627 with 30,000 men, he was in August joined at Lauenburg by Tilly and Duke Georg of Lüneburg, and by the close of the year had overrun Mecklenburg, Holstein, Slesvig, and Jutland. For this the Emperor made Friedland a hereditary duchy, gave W. (September 1, 1527) the Silesian dukedom of Sagan with Priebus, and made over to him the lands and titles of the two Dukes of Mecklenburg in 1629. As admiral of the Baltic and North Seas he undertook in 1628 to conquer Pommern, but was forced to retire from Stralsund after a costly siege of four months. His arrogance and the growing suspicion of his hidden designs made him many enemies at court, and his chief opponent there was the head of the League, the Elector of Bavaria. After the Edict of Restitution and the landing of Gustaf Adolf (q. v.) in Pommern, Ferdinand, finding the aid of the League necessary, was driven at the diet of Regensburg in 1630 to dismiss W., who at once retired to live in regal splendour on his estate at Gitchin. The success of the Swedes soon compelled Ferdinand to recall W., who with great difficulty was prevailed upon (April 1632) to levy an army of 50,000 men. The Edict of Restitution was recalled, and W. received unlimited power as generalissimo of the empire, Austria, and Spain, till the conclusion of peace. Quickly driving the Saxons from Bohemia, he pushed on to Nürnberg to clear Bavaria of the Swedes, and repulsed Gustaf Adolf at Fürth (August 24). Turning aside to Sachsen, he was decisively defeated by Gustaf Adolf at Lützen (q. v.). Executing the officers to whom he attributed his defeat, W. entered Schlesien in the spring of 1632. In June the Saxon Elector had almost concluded a treaty with W., who hoped now to establish a general peace, gaining the Palatinate for himself. Having cleared Schlesien of its Swedish garrisons, he checked the advance of Bernhard of Weimar by a dash at Regensburg, and returned in December to winter in Bohemia. The intriguing Spanish ambassador, Oñate, at length persuaded Ferdinand to dismiss W., and continue the war in alliance with Spain. In the beginning of February, Gallas, Aldringer, and Piccolomini were secretly won over to the court. On the 24th W. entered Eger. On the night of the 25th, Colonel Butler, with the Scotchmen Gordon and Leslie commanding there, having struck down the generals Ilow, Terska, and Kinsky at a banquet, an Irish captain, Devereux, assassinated W. in his bedroom. Of all the leaders of the Thirty Years' War, W. alone conceived a true idea of German unity. But his efforts to establish peace on a basis of religious liberty were frustrated by his devotion to a misguided emperor, and the delusive hope of founding stable institutions by military power. W. had faith only in himself and his science of astrology. 'Cassandra-like, he was wiser than all the world, and was trusted by none.' Schiller has enshrined in noble drama the memory of the 'last supremely able man of his time, whose life was spent in battling against the great evils of the land, the spirit of religious intolerance, and the spirit of division.' The chief work on W. is Ranke's *Geschichte W.'s* (Leip. 1869). See also the works cited under THIRTY YEARS' WAR.

Wall'er, Edmund, an English poet, born at Cobshill, Hertfordshire, March 2d, 1605, was the son of Robert W., and cousin of John Hampden, and thus a distant relative of Cromwell. He was educated at Eton and King's College, Cambridge, and when his father died in 1616, the year of Shakespeare's death, he was left with estates worth £3500. About his eighteenth year he obtained a seat in Parliament, and wrote his first extant poem, *On the Danger of His Majesty, escaped in the Road at St. Undens.* His first wife, Anna Banks, married in 1631, having died about four years after, the poet successively wooed in verse, and it may be supposed in prose, Lady Dorothy Sidney, whom he styled *Sacharissa*, and Lady Sophia Murray, whom he styled *Amoret*; but failed in both his suits. In 1640 he was selected by the House of Commons to support the impeachment of Justice Crawley for his advocacy of the obnoxious ship-money. In 1643 he was appointed one of the commissioners of the Parliament in the Oxford negotiations with the king, but before the year was out he was found concerned in a plot to seize the leading members, and after a year's imprisonment in the Tower, and the payment of a fine of £10,000, he had to leave the country. He was in Venice in 1646, in Rouen in 1647, and there married a French lady, Marie Bresse or Breaux. In 1653 he obtained permission to return to his native land; two years later he was addressing a *Panegyric to my Lord Protector.* Five years more, and he was equally ready with verses *To the King upon his most happy return*, but the verses were not quite so good as those to Cromwell, and when the king was quick enough to tease him with this inferiority, the poet was witty enough to make the famous excuse—'*Poets, sir, succeed but in fiction.*' He was a member of the king's first Parliament, May 1661, and occupied a similar position for many years after. His death took place at Beaconsfield, near which he had a house, at Hall Barn, October 1687. W.'s poems first appeared in 1645, in three separate editions; other five editions were published in his lifetime, and they have been frequently reprinted. His rank in English literature was for a time preposterously high: Atterbury spoke of him as the parent of English verse, and Hume as the first refiner of English poetry, at least of English rhyme. A few of his pieces are very polished and pretty, and a line of terse vigour or new-coined and brilliant metaphor now and then comes as a surprise. See the Life prefaced to Bell's edition of W.'s poems (new ed. Lond. 1871).

Wall'flower (*Cheiranthus*), a genus of long-podded *Cruciferæ*, familiarly represented by the garden favourite the gilly-

flower or common W. (*C. Chiari*). This plant is a native of central and southern Europe, and has long been naturalised in Britain. It is prized for its early flowering and its sweet fragrance. The wild plant bears bright-yellow or orange-yellow single blossoms, but by the gardener's skill double flowers, varying in colour through red, purple, and brown, have been obtained and are commonly current. There are 12 species of W. distributed through the temperate and cold regions of the N. hemisphere.

Wall'ingford ('the ford at the wall or fortification'), a market-town of Berkshire, England, 14½ miles N.W. of Reading by rail, on the right bank of the Thames, which is here spanned by a bridge (1809) 900 feet in length. Of its three churches, St. Leonard's is an old Norman edifice, St. Mary's was built from the materials of a castle (erected by Stephen 1146, and dismantled by the Parliament 1653), and St. Peter's was rebuilt (1769) by Sir William Blackstone, whose tomb it contains. W. carries on a considerable agricultural trade, and publishes one weekly newspaper. Pop. of parliamentary borough, which returns one member (1871) 8353; of municipal borough, 2972. A Roman station, W. gave its name to a treaty between Stephen and the future Henry II. (1153), and it was captured by Fairfax in the Great Rebellion, since which period it has dwindled in importance.

Wall'is, John, D.D., F.R.S., an English mathematician and divine, was born November 23, 1616, at Ashford in Kent. He entered Emmanuel College, Cambridge, at sixteen, and after graduation was elected a Fellow of Queen's in 1640. During the Civil War he was of great service to the parliament in deciphering secret correspondence. In 1644 he became secretary to the Westminster Assembly, holding at the same time the living of St. Gabriel, Fenchurch Street. About 1647 he turned his attention to mathematics, and was appointed Savilian Professor of Geometry at Oxford in 1648. In 1655 he published his *Arithmetica Infinitorum*, and the next year became involved in a controversy with Hobbes regarding a quadrature of the circle. He wrote numerous other mathematical works on proportion, mechanics, &c., besides re-editing part of the works of Horrocks, Archimedes, Ptolemy, Aristarchus, and Pappus. These were collected and published in 3 vols. (1699). W. was also author of an English grammar written in Latin (1653), a treatise on logic (1687), and various theological works. He died at Oxford, October 28, 1703. His fame rests upon his *Arithmetica Infinitorum*, in which he displays a singular faculty for summing infinite series. Of this nature is his famous value for π, namely,

$$\frac{\pi}{4} = \frac{2 \cdot 4 \cdot 4 \cdot 6 \cdot 6 \cdot 8 \cdot 8 \cdot 10 \cdot \ldots\ldots}{3 \cdot 3 \cdot 5 \cdot 5 \cdot 7 \cdot 7 \cdot 9 \cdot 9 \cdot \ldots\ldots} \text{ to infinity.}$$

A biography of W. is prefixed to the collected edition of his sermons published in 1791.

Walloons', the descendants of the old Gallic Belgæ mixed with Romanic elements, occupying the extreme north-eastern territory of the *langue d'oïl*, viz., the Belgian provinces of Hainault, Liège, and Namur, Southern Brabant, Western Luxembourg, and a few villages round Malmedy in Rhenish Prussia. In Belgium their number is estimated at 2,250,000. Livelier than their Flemish, more hardy and industrious than their French neighbours, the W. make excellent soldiers, and have produced one famous general, Tilly. Their dialect, termed *lingua Wallonica* as early as 1136, has retained more Celtic elements than French, from which it is further distinguished by its copious borrowings from Low German (*e.g.*, of the letters *k* and *w*) and by such phonetic changes as the apocope of *ll* and *gn*, in *coy* = *cueillir*, and *champion* = *champignon*. Its scanty literature dates from the beginning of the 18th c., the earliest drama being *Si Ligeoi egagi* (1757) of J. J. Fabry, prior to which Rickman had published a satire on watering-places, *Les Aiw di Tonk*. See Simonon, *Pöesies en Patois de Liège* (Li. 1845); Grandgagnage, *Dictionnaire Etymologique de la Langue Wallonne* (2 vols. Li. 1845–51), Van der Kindere, *Recherches de l'Ethnologie de la Belgique* (Bruss. 1872).

Walls'end, a village of Northumberland, England, 4 miles E.N.E. of Newcastle by rail, on the left bank of the Tyne, was so called from its position at the eastern extremity of the Roman Wall, and itself gave name to a variety of coal raised from a colliery which was opened in 1777. Now, however, 'W. coal' is applied to all coal passed through a five-eighth inch sieve. W. has a parish church (1809), four chapels, and a temperance hall. Pop. (1871) 4100.

Wall-Trees, in horticulture, are fruit-trees trained against the surface of walls, thereby securing to them an increase of temperature and protection from high winds. The materials of the walls may be brick, stone, earth, concrete, or wood, but the first is by far the best, retaining more warmth than the others, and giving numerous joints for holding the fastenings of the W.-T. Twelve feet is a convenient height for the wall, though for pears and vines it may be half as much again if desirable. The different modes of training W.-T. may be reduced to three forms or systems—the fan or palmate form, which is the most natural mode and that most generally applicable; the horizontal system, which is adapted to trees with strong stems and of long duration; and the perpendicular system, which is chiefly adapted to climbers, such as the vine. Wall-training renders the fruit-trees more prolific, improves the quality of the fruit, permits the production of fruit in the open air which otherwise could only be obtained under glass, and confines the trees within a limited space.

Wal'nut (Old Eng. *wealh-hnut*, 'the foreign nut') is both the tree-name and the name of the fruit of the *Juglans regia* of botanists, and has been popularly extended to comprise all the species of this important genus of *Juglandaceæ*. The order is distinguished from its allies by having alternate, pinnate, often aromatic leaves, without stipules; monœcious flowers, the male congregated into catkins, and the female solitary; an inferior 1-celled ovary furnishing at maturity one oily seed destitute of albumen. It consists of five genera, of which *Juglans* is the most important; and of its constituents the common W. is the best known and most valuable. This species is a long-lived large tree with velvety young shoots, has imparipinnate leaves of 3–6 pair of eliptic-oblong leaflets; the male catkins are cylindric and 2–5 inches long, the individual flowers having 6 perianth lobes and 10–20 stamens; female flowers 1–3; fruit green, ovoid, glabrous, 2 inches long, enclosing a brown irregularly-furrowed nut which is 2-valved, divided by 2 thin coriaceous dissepiments into 4 incomplete cells. As a timber-tree the heart-wood is very durable, works well, and does not split or warp; it takes a fine polish, and is a beautiful furniture wood. Its principal use is for furniture and gun-stocks; it is also employed for turning and fancy articles. The bark possesses dyeing and tanning properties. But the most important product of the tree is its fruit, which forms a favourite item of dessert, and in the young state makes a very good pickle. The husk yields a dark-brown dye. In France an oil is expressed from the kernel serving as an article of diet and used in the preparation of fine colours. The W. is wild in many forests of N.W. Himalaya and in Sikkim, in trans-Caucasia, and probably in Armenia. In Western Europe it is grown nearly to 58° N. lat. (in Ross-shire), but only in sheltered places. Near Edinburgh the tree grows with vigour, but ripens its fruit only in the finest and hottest summers. On the E. side of Europe it is found to 52°. The tree was known to the ancients, and Pliny states that it was brought from Persia. Other noteworthy species of *Juglans* are the black W.-tree (*J. nigra*) and the Butternut-tree (*J. cinerea*) —both forest-trees of N. America. The first attains a height of 70 feet, has a strong, tough, purplish-brown wood, which for its compactness, durability, and its susceptibility to high polish, is much sought for as a furniture wood, and has been largely used of late for gun-stocks. The second is a smaller tree, and its wood is lighter than the black W., but it is equally durable, is not liable to split, is not liable to the attacks of insects, and is in much demand for panels of carriages, corn-shovels, wood dishes, &c. The leaves, bark, and husk are used for medicinal purposes.

Wal'pole, Sir Robert, an English statesman, was born at Houghton in Norfolk, August 26, 1676, and educated at Eton and King's College, Cambridge. On entering Parliament he attached himself to the Whig party, and was successively appointed a member of the Council of the Admiralty (1705), Secretary of War (1708), and Treasurer of the Navy (1709). His defence of the financial policy of the fallen Godolphin aroused the enmity of the Tories, and on a charge of corruption he was expelled from the House of Commons, and imprisoned for some months in the Tower (January 17, 1712). The borough of King's Lynn, however, returned him to Parliament in 1714, and not long afterwards his known zeal for the Hanoverian succession procured him rapid promotion under the new king, George II. In 1715 he became First Lord of the Treasury and Chancellor of the Exchequer; but in 1717, on a division in the

cabinet, he resigned. The disastrous effects of the South-Sea Scheme having rendered his financial services of prime importance to the nation, he returned to power in 1721, and for the next twenty-one years, in spite of a powerful, persistent, and versatile opposition, he kept his seat at the head of the Government, crushing all insubordination among the members of his cabinet, and venturing at times to go in the teeth of the popular will. At length in 1742 he resigned office, accepted the earldom of Oxford and a pension of £4000, and retired into private life. He died in 1745. W.'s political character has been very variously judged, but no one can venture to deny him the possession of high capacity and skill, especially in matters of finance. He was ambitious and fond of power, showed little delicacy in the acquisition of wealth, and acted very consistently on the maxim that a price may be found for any man and any woman. But even his political opponents admit that the charges of corruption brought against him were in great part falsehood, and in great part exaggeration. It was mainly by him that England was saved from a disputed succession; it was almost solely to him that she was indebted for the long peace which allowed her commerce and industries to develop; he began to reduce the national debt; he encouraged the commerce of the colonies, and he laid the basis of free trade. See Coxe's *Life of Robert W.* (3d ed. 1816, 4 vols.); *Walpoliana* (privately printed by Lord Hardwicke in 1783); Mahon's *History of England*, 1713–83 (5th ed. Lond. 1858); Ewald's *Sir Robert W., a Political Biography* (Lond. 1877); Lecky's *History of England in the Eighteenth Century* (Lond. 1878); Macaulay's *Essay on Horace W.'s Letters*; and Carlyle's *Life of Frederick the Great*.—**Horace W.**, generally believed to be the third son of Sir Robert W., was born October 5, 1717, and received his education at Eton and Cambridge. Along with his old schoolfellow Gray, he spent the greater part of two years on the grand tour, and on his return home in 1741 he entered Parliament. But though he kept his seat, now for one borough and now for another, as late as 1768, he took almost no part in the business of the House; and indeed after 1747, when he purchased a small estate near Twickenham, he devoted the greater part of his attention to the extension and improvement of his 'rural bijou,' which was gradually transformed into a fantastic Gothic castle—the well-known Strawberry Hill. In 1757 he started a printing-press. Gray's two odes were the first productions of his press; and in 1758 he issued his own *Catalogue of Royal and Noble Authors*. During the latter part of his life he felt a great attraction to Paris. He was there in 1765, in 1767, in 1769, and in 1775; and on the second occasion he formed a warm friendship for Madame Du Deffand, '*who loves* me as much as my mother did.' The death of his nephew, the third Earl of Oxford, in 1791, gave him possession of his father's estate and titles; but he only survived to enjoy them for six years, dying on the 2d of March 1797. W.'s *Letters* rank him among the finest letter-writers in the English language; his *Castle of Otranto* was one of the earliest novels of the Romantic school; and his *Anecdotes of Painting in England* (based, however, on George Vertue's collections), formed for a time the best work on the subject. *Letters to George Montague*, 1736–70, were published (Lond. 1818); *Letters to Rev. William Cole, &c.*, 1745–82 (Lond. 1818); *Private Correspondence*, 1735–97 (1820, 4 vols.); *Letters to Horace Mann*, 1741–60 (1833, 3 vols.); and *Letters to H. Mann*, 1760–85 (1843–44, 4 vols.). *Letters to the Countess of Ossory* appeared in 1848, and *The Correspondence with Mason* in 1850; and finally a collected edition of all the letters, arranged chronologically, was published by Peter Cunningham (1857–58, 9 vols.). Among W.'s other works are *Historic Doubts in Life and Reign of King Richard III.* (1768); *Memoirs of the Last Ten Years of the Reign of George II.* (1822, 2 vols.); *Memoirs of King George III.* (1845, 4 vols.). See Warburton, *Memoirs of Horace W., &c.*, (Lond. 1851, 2 vols.); Macaulay, *Essay on Letters of Horace W.*; *Lettres de la Marquise du Deffand à Horace W.* (Par. 1864, 2 vols).

Walpur'gis (*Walburg*, 'shielder of the fallen,' *cf.* VALKYRJUR), **Saint**, sister of St. Willibald, died in 779, abbess of Heidenheim near Eichstädt. The day of her canonization (May 1) chancing to fall on that of one of the chief heathen festivals, the feast of spring, the *Walpurgisnacht* (between April 30 and May 1) came to be superstitiously regarded as the night when the witches danced with the devil on the Blocksberg.

Wal'rus. See MORSE.

Wal'sall, a town of Staffordshire, 8 miles N.N.W. of Birmingham by rail. It is situated on a small affluent of the Tame, and has good public buildings, including a Guildhall (1867), an Agricultural Hall (1868), a new church of St. George, erected 1875 at a cost of £7000, and a Cottage Hospital, opened in 1878. The special manufactures are saddlers' ironmongery and all kinds of leather goods (saddles, harness, &c.), the latter being largely exported to America and the colonies. There is much tanning, currying, bridle-cutting, and making of coachbuilders' furniture and fancy leather wares. W. lies on the margin of the S. Staffordshire mineral field, and produces a great variety of hardware, small castings, gas tubes, chandeliers, iron bedsteads, silver and brass plating, &c. Coal and lime are wrought in the vicinity. W. sends one member to Parliament, and publishes three newspapers. Pop. (1871) 49,018.

Wal'singham, Little, a village of Norfolk, England, 38¾ miles N.W. of Norwich by rail, has the ruins of an Augustinian priory, founded under the Conqueror by Geoffroy de Favarches. Its shrine of Our Lady of W. well-nigh outrivalled that of St. Thomas of Canterbury for popularity, and among the pilgrims who flocked to it were Henry VIII. and Erasmus. See the latter's *Peregrinatio Religionis ergo*, and the Introduction to Nichols' translation (2d ed. Lond. 1875).

Wal'singham, Sir Francis, was born of a good old Kentish stock at Chiselhurst, in 1536, and after finishing his course at King's College, Cambridge, became by foreign travel the finest linguist of his times. Cecil bred him his agent, and in 1570 sent him upon an embassy to France, and so skilfully did he beguile the Duc d'Anjou, that at his return (1573) he was taken for one of the principal secretaries of state, knighted, and sworn of the Privy Council. In 1578 he was a commissioner for the settlement of the Netherlands; in 1581, the year that Monsieur was courting the Virgin Queen, he revisited France, 'there playing,' says Naunton, 'the very same part that Gondomar since did here;' and in 1583 he 'altered the government of Scotland as ambassador.' Scotland and France alike by praying for his recall acknowledged his abilities, but these were to be yet more signally displayed. By suffering Babington's Conspiracy (1586) to come to a head, by intercepting letters, and, after deciphering, forwarding them to Mary Stuart (q. v.), he compassed the death of that unhappy queen, for which singular loyalty to his mistress he was created a knight of the garter, chancellor of the duchy of Lancaster, and recorder of Colchester. His principal merit is that with all his lucrative posts he was not rich when he died at Barn Elms, 6th April 1590, leaving a daughter who was successively wife to Sir Philip Sidney, the Earl of Essex, and the fourth Earl of Clanricarde. The eulogists of W. dwell with such admiration on his motto, 'Tell a lie and find a truth,' on his fifty-three agents and eighteen spies, and on 'the seeds of division that he sowed as the fiend in the Gospel tares,' that they have few words left for his learning, his powers of discourse, and his devotion to Elizabeth. See Naunton's *Fragmenta Regalia* (Lond. 1641), and Froude's *History of England* (vols. vii.–xii.).

Wal'tham, a small town of Massachusetts, U.S., on the Charles River, about 9 miles W. of Boston, with which it is connected by rail. It has several churches, a public library, schools, &c., but is chiefly noted for its extensive manufacture of watches (see WATCH). Pop. (1878) 9065.

Wal'tham Abbey, a market-town of Essex, England, on the Lee, 14 miles N. of Shoreditch by rail. Of the cruciform Romanesque church of Holy Cross only the nave and lady chapel remain, but these (restored in 1860–75) sufficiently attest the former grandeur of a structure whose erection is variously ascribed to Harold (*e.g.* by Mr. Freeman) and Henry I., and which was probably the last resting-place of the first-named king. There are besides six chapels, four schools, a court-house, and police-station (1876), and on the Lee is a large government factory of gunpowder and saltpetre. Pop. (1871) 5197. See, for the history of the Abbey Church, Prof. Stubbs' Introduction to his edition of the tract *De Inventione Sanctæ Crucis in Monte Acuto et de Deductione ejusdem apud Waltham* (Oxf. 1860).

Walther von der Vogelweide, was born of poor but noble parents between 1157 and 1167, probably in S. Tyrol. He lived first at the court of Friedrich of Austria, on whose death in 1198 he joined the party of Philipp of Hohenstaufen. He was present

at Philipp's coronation at Mainz, and thereafter stayed sometime with Hermann, Landgraf of Thüringen. After Philipp's assassination W. attached himself to Friedrich II., whom he accompanied to Palestine in 1228. W. was the greatest German lyrist of the Middle Ages, equally eminent in *Minnelied* and patriotic song. The chief editions of his poems are by Lachmann (4th ed. 1864), Wackernagel and Rieger (1862), and Pfeiffer (5th ed. 1877). See Gosse, *Northern Studies* (1879).

Wal'ton, Brian, born in 1600 at Seymour in Cleveland, Yorkshire, studied at Magdalen College and Peterhouse, Cambridge, and after graduating (1619) kept school in Suffolk. He became rector of St. Martin's Ongar, London, and Sandon in Essex (1635), chaplain to the king and a prebendary of St. Paul's (1639), but was sequestered from all these offices by the Parliament in 1642, having rendered himself obnoxious to the Puritans by his *Treatise on the Payment of Tithes and Oblations in London* (1641). Taking refuge in Oxford, he there designed the famous Polyglot (q. v.) that bears his name, and which in spite of infinite disturbances for his loyalty he completed in four years' time. At the Restoration he was rewarded with the bishopric of Chester, but died in London, 29th November 1661. His works, which include an *Introductio ad Lectionem Linguarum Orientalium* (1655), and an answer to Owen's *Vindication of the Purity of the Hebrew and Greek Texts* (1658), are enumerated in Todd's *Memoirs of W.'s Life and Writings* (2 vols. 1821).

Wal'ton, Izaak, was born at Stafford, August 9, 1593. About 1623 we find him carrying on business on his own account as a sempster or man-milliner in London, and having by 1643 acquired a competency, he retired to the quiet enjoyment of country life. His first wife, Rachel Floud, great grand-niece of Archbishop Cranmer, having died in 1640, he married about seven years later Ann Ken, whose brother, at that time a mere boy, afterwards became the famous bishop. In London W. had become intimate with Dr. Donne, Dr. Wharton, and Sir Henry Wotton, and in his later years he enjoyed the hospitality of many eminent clergymen of the Church of England. He died at Winchester, 15th December 1683. W.'s fame is mainly based on his *Compleat Angler; or the Contemplative Man's Companion*, which was first published in 1653 and appeared in a considerably modified form in 1655. Few more popular books exist in English, and the editions are consequently numerous. It is sufficient to mention those of Dr. Hawkins (1760) and Sir N. H. Nicholas (1833), and the *fac simile* reprint of the first edition, published by Elliot Stock in 1870. Full bibliographical detail will be found in Thomas Westwood's *Chronicle of the Compleat Angler* (Lond. 1864). W.'s natural history is frequently of the crudest and most credulous kind; his practical precepts are open to correction at the hands of the modern proficient; he possesses only a partial mastery over the difficult literary form (that of the dialogue) in which his work is cast; his style is remarkable neither for rugged strength nor polished precision; but he has succeeded in catching the spirit both of the gentle craft and the pleasant English scenery in which he had learned its delights. On the publication of Dr. Donne's *Sermons* W. supplied a Life of the author, and he afterwards wrote similar lives of Wotton, Hooker (1665), Herbert (1670), and Sanderson (1678). Among the complete editions of these lives, which are characterised by much the same features as the *Compleat Angler*, the most important are Dr. Thomas Zonch's (York 1796), Major's, with plates (Lond. 1825), and Washbourne's (Lond. 1857). A monument to W. was placed in St. Mary's, Stafford (the church of his baptism), in 1878. W.'s own Life has been written by Hawkins, Sir N. H. Nicholas, and W. Dowling. See also Shepherd's *Waltoniana: Inedited Remains* (Lond. 1879).

Waltz (Ger.; Fr. *valse*), the most popular and fashionable of round dances. It is in three-fourth time, and is performed by a couple who turn incessantly round and at the same time make a circuit of the room. From Bohemia it became the national dance of Germany, whence it was introduced into France about 1790. The French, however, claim a Provençal dance called the *volta* as the original of the W. Be this as it may, notwithstanding the popularity of the dance all over the world, Germany is still its peculiar home. The finest W. music is German: the great composers Beethoven and Weber have not disdained to embellish it with their genius, while the most rhythmical, elegant, and seductive of modern dance music is to be found in the strains of Strauss, Gung'l, and other musicians of the Fatherland. The W. is frequently set to words, and forms a favourite theme in operas. In dancing the valse a *trois temps* is most used.

Wam'pum, the N. American Indian name for shells or shell-beads used as currency. They are sometimes strung together and worn as a belt for ornament.

Wanderoo' Monkey (*Silenus veter*), a species of *Catarhine* or Old-World monkey, occurring in the E. Indies and Ceylon, and distinguished by the well-developed hairy covering of the head and neck, while the sides of the head and chin are also bearded. The tail is of moderate length and tufted. The colour of the fur is a deep or jet black, and the callosities on the buttocks are a bright pink. The length of the W. is about 3 feet. In some respects this monkey is regarded as relating the Macaque, with which it is usually classified, to the Baboon.

Wan'dewash, a town in the district of S. Arcot, Madras Presidency, British India, 73 miles S.W. of Madras, famous for the victory gained in December 1759 by the British under Colonel Eyre Coote over the French under Lally and Bussy. It led to the capture of Pondicherry, and was the decisive battle which established the supremacy of the British in the Carnatic, after an almost continuous war of fifteen years. In 1781, W. was heroically and successfully defended against Hyder Ali.

Wan'tage, a market-town of Berkshire, England, in the Vale of the White Horse, 10 miles S.W. of Abingdon, is connected by a steam tramway (1875), the first in England, with a Great Western station at W. Road, 2½ miles distant. It has a cruciform Second Pointed church (elaborately restored, 1857; enlarged, 1878), a corn exchange (1865), an Anglican house of mercy, a grammar-school (1850; enlarged 1877), &c. The Vale of White Horse Foundry is the only important manufactory of W., which has published since 1875 one weekly newspaper. Pop. (1871) 3295. At W., in 849, Ælfred the Great was born, and on July 14, 1877, a statue of him, of Sicilian marble, 8 feet high, and mounted upon a granite pedestal, was unveiled by the Prince of Wales in W. market-place.

Wap'enshaw ('weapon show'), in Scotland, a semi-military gathering enforced by various statutes during the 15th and 16th centuries. These directed that individuals should carry certain arms, according to their rank and property, and that they should, when summoned by sheriff or magistrate, rally round the king in time of war. On account of the merrymaking with which in later times wapenshaws became associated, they were discouraged by the Covenanters.

Wap'entake (Old Eng. *wæpen*, 'weapon,' and *tac*, 'touch'), a territorial designation in Yorkshire, corresponding to the *hundreds* of the southern counties, and to the more northern *wards*. It refers to the defensive military organisation of the Danish intruders, as distinguished from the more peaceful Hundred (q. v.).

Wap'iti (*Cervus Canadensis*), a typical and elegant species of deer, often named the Carolina stag, and found in N. America; where it is also popularly known as the 'Elk.' The adult W. may measure 5 feet in height at the shoulders, and attains a length of over 7 feet. The colour resembles that of the ordinary British deer, but the fur grows darker. The W. lives in large herds, and the antlers resemble those of the Stag (q. v.). The flesh is dry, but the hide furnishes a durable leather.

War, in its international sense, is a military contest between the armed forces of two or more states or nations; in its civil sense, a conflict between parties of the same state. International wars usually arise from disputes about territorial possessions and frontiers, unjust dealings with the subjects of one state by another, sympathy with struggles for liberty by persecuted nations, questions of race and sentiment, jealousy of military prestige, or desire of conquest. Civil W. is waged for political, religious, or social objects. W., though a great curse, seems in some cases an absolute necessity; and while human passions rage and human sufferings exist, it were vain to look for a cessation of its horrors. The country that sets its face absolutely and in all cases against it must expect to lose its position among the nations of the world, while that which needlessly rushes into its desperate meshes brings untold evil upon its people. A state of preparedness for W. is often the greatest security for peace, or at any rate is regarded as such, and hence arise the colossal standing

armies of the Continent, with their stern laws of military service. Wars are aggressive on the part of a state beginning hostilities with a hitherto friendly power, defensive on the part of a state which repels such aggression. Before the commencement of hostilities among civilised nations, the state taking the initiatory step issues a Declaration of W., which usually takes the form of an explanatory manifesto to neutral powers. The great aim in W. is the destruction of the enemy's military power, thus compelling him to sue for peace, upon the conclusion of which adequate securities are usually taken that the defeat shall be complete and effective against any fresh outbreak. In the prosecution of W. the fundamental principle is the bringing of the strongest possible force upon the weakest point of the enemy, and the using of such force with the greatest possible velocity. See ARMY, ARTILLERY, STRATEGY, TACTICS, &c. The end aimed at is often the possession of the enemy's capital, which by forcing the sovereign and legislature away from the centre of the state, paralyses trade and government, and must, if undefeated, compel the enemy to come to terms. The advantage in W., other things being equal, lies with the army strong enough to take the initiative, and to make the enemy's movements dependent on its own. The influence of modern science and appliances upon wars has been to shorten their duration, none of the four great European wars since the conflict in the Crimea having lasted a year. The loss of life has not, however, diminished in proportion, and the prosecution of a W. has become much more costly. Thus the civil war in America from 1861 to 1865 cost £800,000,000, or four times as much as 13 years of W. cost France under the First Empire.

The laws of war among civilised states permit the destruction or capture of armed enemies, the destruction of property likely to be of service to them, the stoppage of all their channels of traffic, and the appropriation of everything in an enemy's country necessary for the support and subsistence of the invading army. A victorious army seizes all public money and public property. Deserters from an army or enemies who have broken their parole are shot. Captured spies are hung. It is lawful to starve an enemy into surrender. But as far as possible wars are conducted with respect to the feelings of humanity and mercy. Wounding, except in battle, mutilation, and all cruel and wanton devastation, are illegal. All pillage and maltreatment of unarmed enemies is prohibited, but if such enemies rise against an army in possession, they violate the laws of war. The subjects of enemies cannot be forced into the service of victors, and their private property must be respected, although it may be temporarily appropriated for military purposes. All wounded prisoners should have medical treatment, and no punishment is due to a public enemy after his capture unless for crimes previously perpetrated against his capturers, violators of the laws of W. not being entitled to their protection. The use of the enemy's national flag is such a violation. The person of the bearer of a flag of truce is sacred, but firing is not required to stop on the appearance of a flag of truce during a battle. Hospitals are usually protected by special flags, and deception by designating other places in this way is considered infamous.

In naval warfare, ships of war are used for transport and blockade, for holding certain strategical positions, and for destroying the naval resources and armaments of the enemy. Shelling an unprotected town, and privateering, are considered illegal.

War'asdin, a frontier town in the comitat of W. Croatia, Austria, on the Drave, 28 miles N.E. of Agram. It has nine Catholic churches, a collegiate chapter, two monasteries, an upper gymnasium, and an old chateau. Its S. side is defended by redoubts. W. manufactures tobacco, stoneware, rosoglio, and silk. Pop (1870) 10,623.

War'beck. See PERKIN WARBECK.

War'bler (*Sylviadæ*), a very large family of *Dentirostral* birds, in modern systems of ornithological classification divided into a great number of subordinate groups. Some authorities have entirely discarded this family as too general for scientific arrangement. The typical genus *Sylvia* has a few weak bristles at the base of the bill, and the nostrils in a short groove. The first quill is short, and the third and fourth quills are the longest. The hinder toe has a strong claw. The sub-family *Luscininæ* may be regarded as including most of the species and genera formerly included in the family *Sylviadæ*. The best-known species are the Whitethroats, the Garden W., Willow W., Wood W., and Blackcap W. The Grasshopper W. (*Calamodyta locustella*) belongs to a different genus of W. from the preceding; and the Sedge W. (*C. phragmitis*) is a second species of the genus *Calamodyta*. The genus *Salicaria* includes the Fantail W. (*S. cisticola*) found on the Mediterranean coasts.

War'burton, William, D.D., an English divine, the son of an attorney, was born at Newark, December 24, 1698. On leaving school (1714) he was articled to his father's profession, and in due course having been admitted at one of the courts of Westminster he began to practise at Newark. At the end of four years, however, he determined to enter the church, and he was accordingly ordained deacon in 1723 and priest in 1727. His first publication was *Translations in Prose and Verse from Roman Poets, Orators, and Historians* (1724). The vicarage of Greaseley (1727), the rectory of Brant-Broughton (1728), the chaplaincy to the Prince of Wales (1738), a prebend of Gloucester (1753), a prebend of Durham (1755), and the deanery of Bristol (1757), were the principal steps of preferment which at length, in 1760, brought him to the bishopric of Gloucester. In the meantime he had gradually taken rank as one of the greatest theological writers of his time, and by sheer force of colossal self-assertion had attained to a kind of despotic supremacy. His principal work is an unfinished treatise on the *Divine Legation of Moses*, of which books i., ii., and iii. appeared in January 1737-38, and books iv., v., and vi. in 1741, while the vii. and viii. were probably never written and the ix. found only posthumous publication. The main argument is a worthless paradox: a belief in future retribution is necessary for the maintenance of all human society; the Jews had no knowledge of a future state; therefore the national existence of the Jews can only be explained on the hypothesis that they received supernatural support; and therefore the legation of Moses is divine. Around this cardinal paradox is collected an amazing mass of lesser paradox and erudition, while many incidental subjects are treated with great originality. Besides the *Divine Legation* his most important works are a *Critical and Philosophical Inquiry into the Causes of Prodigies and Miracles* (1728), and *The Alliance between Church and State* (1736). When in 1738 M. de Crousaz accused Pope of giving currency to infidel doctrines in his *Essay on Man*, W. published seven letters in the poet's defence (*A Vindication*, &c.), and the friendship thus established between the theologian and his protégé proved of great importance to both. A collected edition of W.'s works (7 vols. 1788) was brought out by his friend and henchman Bishop Hurd, and a supplemental volume appeared as a *Discourse by way of Preface* in 1794. A new edition in 12 vols. was published in 1811. See, besides the panegyrical account by Hurd (*u. s.*), J. S. Watson's *Life of W. W.* (Lond. 1863), Isaac Disraeli's *Calamities and Quarrels of Authors* (new ed. 1865), Hunt's *Religious Thought in England* (Lond. 1873), and Leslie Stephen's *English Thought in the Eighteenth Century* (Lond. 1876).

Ward, Artemus. See BROWNE, CHARLES FOSTER.

Ward, Edward Matthew, R.A., an English historical painter, was born at Pimlico in 1816, was admitted a student of the Academy in 1834, and received instruction from Wilkie. After studying at Rome (1836-38) he gained the silver medal of the Academy of St. Luke, and applied himself to the practice of fresco at Munich under Cornelius. His 'Dr. Johnson Reading the MS. of the Vicar of Wakefield' brought him into notice in 1843. Among his many subsequent works were 'Goldsmith as a Wandering Musician,' 'Dr. Johnson in the Anteroom of Lord Chesterfield,' 'The South-Sea Bubble,' 'James II. receiving Tidings of the Landing of the Prince of Orange,' 'The Royal Family of France in the Temple,' 'Execution of Montrose,' 'Antechamber at Whitehall during the Dying Moments of Charles II.,' 'Johnson and Wilkes,' 'Baxter and Jeffreys,' 'Eve of St. Bartholomew,' and 'William III. at Windsor.' In 1846 W. was made A.R.A., and R.A. in 1855. He was commissioned in 1853 to paint eight pictures for the corridor of the House of Commons, and these include his 'Charles II. assisted in Escape by Jane Lane,' 'The Acquittal of the Seven Bishops,' and 'Last Sleep of Argyle.' He died at Windsor, 15th January 1879.

War'den, Lord. Before the union between England and Scotland the duty of protecting the border counties of the former country from hostile raids was assigned to certain officers called

Lord Wardens of the Marches. The L. W. of the Cinque Ports is a dignitary dating from the days of William the Conqueror. He has a peculiar maritime jurisdiction and the nominal guardianship of the south-eastern coast of England, but the office is almost a sinecure. It gives right to the use of Walmer Castle as a residence. There is a L. W. of the Stannaries (q. v.).

Ward'holding, the military tenure of land in Scotland under the feudal system, under which the vassal was obliged to serve the superior in war, when called on to do so. The tenure, being considered unsuited to the times, was abolished in the reign of George II.; tenures from the Crown being changed into *Blanch*, those of subjects into *Feu*. See FEU.

Ward'ian Cases are boxes covered with tight-fitting frames of glass, under which plants are successfully raised that could not be grown in the vitiated atmosphere of some cities or dwellings. They are named after Mr. N. B. Ward, a surgeon of London, who first announced his discovery to Sir William Hooker in 1836. Plants have been successfully transported long distances packed in W. C. By means of them Mr. Fortune conveyed 20,000 tea plants from Shanghai to the Himalaya, and they have enabled the transport to be effected of the cinchona tree from S. America to India. Mr. W. never received any recognition of his services from the state.

Ward'law, Ralph, D.D., the most eminent name in the history of Scotch Congregationalism, was born at Dalkeith 22d December 1779. He studied at the University of Glasgow, and at the Selkirk 'Hall' of the Burgher Synod; but, becoming dissatisfied with the tenets of that body and of Presbyterianism in general, he embraced the doctrines of the Independents. He held office in that body, first at Perth, then at Dumfries, and finally (1803) at Glasgow. He also (1811) became principal professor of theology at the 'Hall' of his denomination in that town. In 1818, W. received the degree of doctor in theology from Yale College. He died 17th December 1853. His jubilee had been celebrated the previous February. W. wrote a large number of works, chiefly of a polemical character; the chief were—*Discourses on the Socinian Controversy* (1814), *Unitarianism Incapable of Vindication* (1816), *Dissertation on the Scriptural Authority, Nature and Uses of Infant Baptism* (1825), *Discourses on the Sabbath* (1832), *Christian Ethics* (2d ed. 1834), and *National Church Establishments Examined* (1839). Besides these, W. published a number of sermons, a discourse on miracles, and a number of writings in support of the peculiar doctrines of his own sect. W. was a man of very orthodox opinions. These he defended with zeal and ability, and at the same time fairly and moderately. His style is chaste, clear, and vigorous. A certain narrowness observable in his works is to be attributed, not to the man, but rather to the circumstances in which he was placed. See *Life and Writings of W.*, by Dr. W. L. Alexander (2d ed. Lond. 1856); also W.'s lectures on *Systematic Theology* (3d ed. Edin. 1858), and his *Posthumous Works*, edited by his son (8 vols. Edin. 1861-62).

Ward'law, Elizabeth Halket, Lady, a Scottish poetess, daughter of Sir Charles Halket of Pitferrane, was born April 1677, married Sir Henry Wardlaw of Pitreavie in 1696, and died in 1727. She is the authoress of the fine ballad of *Hardyknute*, which was long handed about in MS. as a genuine product of antiquity, and was printed as such by Ramsay in his *Evergreen* (1724). The secret of the authorship was first disclosed by Percy in his *Reliques of Ancient English Poetry* (1755). Lady W. also touched up the ballad of *Gilderoy*; Kirkpatrick Sharpe was 'almost persuaded' that she wrote 'the grand old ballad of *Sir Patrick Spens*,' and finally Dr. Robert Chambers, in a controversial pamphlet, ascribed to her the fabrication of most of the 'historical' Scottish ballads.

Ware, a market-town of Hertfordshire, England, on the Lea, 22½ miles N. of London by rail, has two churches, the cruciform St. Mary's (restored at a cost of £5800) and Christ Church (1858) in Early English style. There are besides four Dissenting chapels; St. Edmund's College (1795), which has a fine church by the elder Pugin, and was the meeting-place of the fourth provincial synod of the Catholic hierarchy (1873); a town-hall, corn exchange (1867), and the remains of a noble priory (1233); whilst among the chief lions of W. is its famous Bed (q. v.), alluded to in Shakespeare's *Twelfth Night* (iii. 2). Malting, brewing, and brickmaking are the chief industries. Pop. (1871) 5403. The name W. is a form of weir or 'dam,' one having been made here by the Danes.

Ware'ham ('the fortified place'), an ancient town of England, in Dorsetshire, situated at the head of a land-locked haven, a branch of the greater one of Poole, on the isthmus of a peninsula formed by the confluence of the southern Frome and Piddle, 32 miles S.S.W. of Salisbury by rail. It is girt on three sides by rectangular ramparts of earth (30 feet high), the origin of which is uncertain. The Norman church of Lady St. Mary contains some fine 13th-c. tombs. The town has shrunk within its wall, but it still has some industry in brewing, malting, and the making of bricks and potter's clay. Pop. (1871) 6532. W. first appears in history in 876, when the Danes marched thither from Cambridge, and, after swearing oaths and giving hostages, marched thence to Exeter in the following year. In the reign of Edward I. W. was a special quarter for the king's housecarls, but of its castle only meagre traces are visible. From Edward's time it sent two members to Parliament; but since the first Reform Bill it returns only one.

Ware'hou'sing System. See EXCISE, and under BOND, BONDED WAREHOUSE. Goods bonded in the warehouse must be so stowed as to leave easy access to each package. The occupier of the warehouse is liable to pay duty if he allows a package to be taken away without entry. Goods must be removed within three years; ship's stores within one. If not, they will be sold to defray rent and charges.

War'ham, William, born about 1450 at Church Oakley, Hampshire, from Winchester was elected scholar of New College, Oxford, of which he became a fellow in 1475. At Oxford he commenced the study of law, and having taken his LL.D., repaired to London (1488) to practise in the Court of Arches. His sober abilities were brought by Archbishop Morton under the notice of Henry VII., who attached him to Poynings' embassy to the court of Burgundy (1493, the probable year of W.'s ordination). His luculent exposure on this occasion of Duke Perkin's claims led to his rapid advancement, and he became precentor of Wells, Master of the Rolls (1494), Archdeacon of Huntingdon (1496), Bishop of London and Lord Chancellor (1502), and Archbishop of Canterbury (1503). The popular minister of an unpopular king, W. was charged with divers important missions, but as an opponent of the marriage to Catherine enjoyed less favour with the Eighth than the Seventh Henry, and in 1515 gladly resigned the Great Seal to Wolsey, having laboured to get quit of it for several years. With Wolsey he always stood on amicable terms, but his chosen friends were the scholars of the New Learning, Colet, Grocyn, Linacre, and Erasmus, all of whom he helped to preferment, which Erasmus repaid by the noble preface to his *St. Jerome*. From lettered retirement W. was called in 1529, weighed down with age and bodily infirmities, by the burning questions of the royal divorce and royal supremacy. On the first he sided passively with Henry, on the second yielded, presenting the submission of Convocation to the King three months before his death at Canterbury, 22d August 1532. He died, indeed, none too soon, since he left a protest that he could never have suffered any derogation of the Holy See, being no 'Reformer,' though favourable towards reform, the suppresser of Tyndal's version, though agreeing with Erasmus that reformation must come from a critical study of the Scriptures, and though wholly guiltless of the persecutions malignantly ascribed to him by Foxe. Learning owed much to his conduct as Chancellor of Oxford; and Erasmus has painted his kindly, witty, simple, open-handed, holy character. See vol. vi. of Hook's *Lives of the Archbishops of Canterbury* (Lond. 1868).

Wark'worth, a seaport of Northumberland, England, on the Coquet, 15¼ miles N.N.E. of Morpeth by rail, has an ancient parish church with a spire 100 feet high, but is chiefly celebrated for its noble castle, a stronghold of the Percies, which, crowning a bold eminence on the right bank of the river, was built in the reign of Edward III., and still uprears its lofty keep and Lion's Tower. The Hermitage of Bishop Percy's poem, with its exquisite little chapel, lies ½ mile distant. The trade of W. is chiefly carried on from Amble, 1 mile to the S.E., on whose harbour £250,000 had been expended up to 1876, and which in

that year had 32 ships. A church, in Early Decorated style (1870), schools (1872), and a pier, quays, tramways, &c., all recently constructed, mark the growing importance of the place, which is due to its vicinity to the great Radcliffe coal-seam. Brickmaking, herring-fishing, and salt manufacture are also carried on. Pop. of W. (1871) 5087; of Amble, 1275.

Warm'-blooded An'imals, the name given to *Mammalia* and *Aves* or Birds, in contradistinction to Fishes, Amphibians, and Reptilia, as lower vertebrata, and to all *Invertebrate* animals. In the latter, the blood is only a degree or two warmer than the medium in which they live, whilst in mammals and birds the blood greatly exceeds the outer temperature in heat. The average mammalian temperature varies from 99° F. to 100° F., as in man and his nearest allies, to 103° F. in the whales. In birds, which are the warmest-blooded animals, the lowest temperature is about 154° F., and may range to 110° or 112° F. This would represent an excessive fever heat in man. In hybernating animals the temperature falls considerably, as the tissue-waste is reduced to its minimum. The production of heat depends on the union of oxygen in the blood with carbon and hydrogen in the tissues; active habits, as in birds, demanding a large supply of oxygen, and producing heat accordingly.

Warm'ing and Ventila'tion. These two questions are so intimately related to each other that the one cannot be discussed without the other; indeed they are only two sides of one subject —the controlling of the air within apartments and inclosed spaces of all kinds. While warming has to do with the temperature of the air only, ventilation is concerned with its purity and fitness for breathing. The question of warming, it will be found, has an important bearing on ventilation; and without the latter, safe and healthy artificial heating would be impossible. W. and V. may thus be said to embrace the science of keeping the air of apartments in that condition most conducive to health and comfort. The necessities of the case as to artificial warming vary, of course, with the climate and mean temperatures of different localities, and these variations also modify the conditions of ventilation. Appliances and conditions, therefore, that are needful and indispensable in Arctic regions are not essential in temperate, and would be very much out of place in tropical latitudes. It is only in cases where the external temperature falls so low as to produce, by the rapid radiation of heat from the body, a feeling of cold, that artificial heating is needful to comfort. In this connection it is necessary to correct a popular misconception to the effect that the animal body receives any actual accession of heat from the warmth of a room, or from other external sources. The body temperature is, as a rule, much higher than that of the air with which it is surrounded, and the object of artificial warming is only to prevent that rapid radiation of heat from the body surface which results in the unpleasant sensation of cold. The most comfortable average temperature is from 60° to 65° F., and the object of artificial warming is to produce and to disseminate through an apartment that amount of heat. For hospitals and sick-rooms a higher temperature is generally requisite than for ordinary apartments. The methods by which artificial warming is effected embrace (1) the open fireplace or grate system, (2) stoves, and (3) heating apparatus. Of these, the most ancient, wasteful, and yet prevalent system, so far at least as concerns dwellings, is the method of heating by the open grate; but apart from its wastefulness, the radiant heat of an open fire is generally allowed to be the most healthy and pleasant, as it affects the body against which it strikes without overheating or contaminating the air through which it penetrates. It is, however, impossible to warm a large hall by radiant heat without enormous waste, as the heating effect decreases in proportion to the square of the distance of any point from the source of the heat. It is only in comparatively recent times that the true principles of constructing and using open fireplaces have been understood, and great discomfort with very little heat was obtained from the huge yawning chimneys, in which great fires blazed in the halls of our forefathers. Of the heat derived from an open fire, one, and by far the larger part, passes up the chimney, and this, although yielding little or no useful heating effect, is essential for the production of a draught to carry away the gaseous products of combustion, and thereby secures the ventilation of the apartment. Of the heat which goes to produce warmth the greater part is due to direct radiation from the fire, but a certain portion is also reflected from the grate and the materials which surround the fire. For efficient radiation it is necessary to carry the fire as near the front of the grate as is possible consistently with the escape of the gases by the chimney, and a grate ought therefore to be wide and deep rather than broad from back to front, as thereby the largest surface of glowing heat is brought forward. The surface in immediate contact with the fire ought to be of firebrick and not of metal, as the bricks retain and transmit a great part of the heat communicated to them, whereas iron, which is an excellent conductor, carries the heat away and passes it up the chimney, or into the mason-work with which it is connected. The outline of a proper grate is such as to secure a proper reflecting surface for the radiant heat which falls on it, and the chimney throat ought to be sufficient to pass the smoke and gases of combustion and no more. These are the principal points attended to in all the numerous forms of ordinary open grates which are now in the market. As, however, a much larger proportion of the heat passes up the chimney than is absolutely required for producing a draught and ventilating the apartment, numerous devices are applied for the utilisation of a portion of the heat which is thus wasted by an ordinary grate. Grates constructed on the principle of utilising the heating effect of the gases in the chimney are known as ventilating grates. A simple form of ventilating grate designed by Douglas Galton illustrates the structure of this form of grate. In it the hot gases pass up a cylindrical iron flue placed within the chimney, and around that flue a current of air admitted from the outside circulates, and being thus heated it is passed into the room by an aperture near the roof. Thus heated pure air is admitted above, while the colder and vitiated air is carried away by the combustion within the open fireplace.

Stoves.—A stove differs only from a grate in not being sunk in the wall of the apartment, and in being so constructed that the fire-bars can be closed over, and thus the combustion regulated at will. The amount of heating effect derivable from a well-constructed stove is much greater than can be obtained from an open fire; and therefore in countries where fuel is dear and the winters are severe, stoves are much more commonly used than grates. The stove is, however, a much less healthy source of warmth than grates. Stoves composed principally of cast-iron heat quickly, and they not only over-dry the atmosphere of the room, but when heated to redness they become permeable to the gases of combustion, and transmit into the air a noticeable proportion of the deadly gas carbonic oxide. Stoves with brick, fire-clay, or earthenware sides, are free from the latter defect, but they heat only slowly, while the ventilation of a room is defective with all kinds. The form of stove used in Russia (fig. 1) is divided into a series of compartments or chambers placed over each other, in the lowest of which the fuel is consumed, and the smoke and hot gases circulate through and heat the whole, which thus present a large radiating surface to the apartment. Dr. Arnott's stove, invented in 1855, was designed to secure improved ventilation, and to utilise the heat without dangerous overheating. It consists of a double-casing (section, fig. 2), air circulating and becoming heated in the outer space, and in the inner firebrick-lined portion the fuel is burned, air being admitted at the bottom, and the product of combustion passing off by a pipe as indicated by the arrows. The Gill stove is a further improvement now generally applied to heating stoves. It was devised by an engineer, Sylvester, and consists of a series of vertical plates thrown out from the outer stove casing, whereby a great radiating surface is secured in a compact and convenient manner. In some

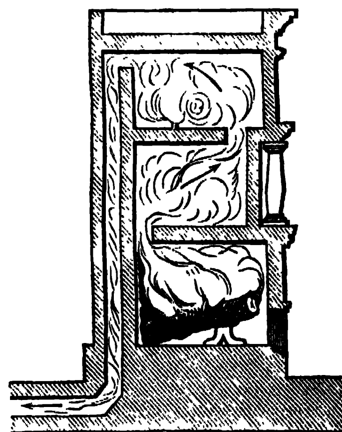

Fig. 1.—Section of a Russian Stove.

stoves there is an arrangement for heating and evaporating water, thus preventing the over-drying of the air, and keeping the stove itself from becoming heated to redness. The modifications of stoves on these principal lines are endless.

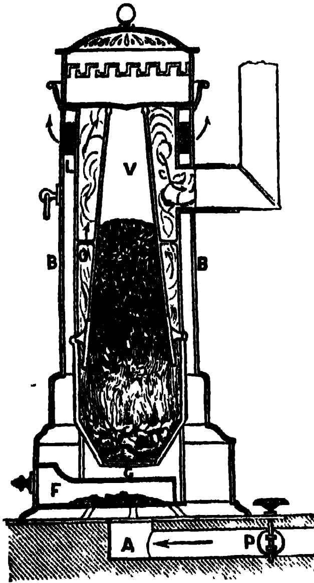

Fig. 2.—Section of Heating and Ventilating Stove. A, Inlet Air Pipe; B, Outer Casing; P, Valve; F, Ash Box; V, Fuel Space; G, Fire-bars; L, Hot Air exit.

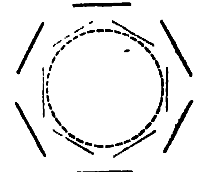
Heating Apparatus is the most economical and cleanly, and for large apartments, schools, and halls the only efficient system of warming. Certain kinds have the additional advantage of being the freest from all risk of fire, as the heat is generated in a space generally set apart for that purpose alone. Under the term heating apparatus are included all forms in which the heat is generated in one place and conveyed by some means to warm one or more separate apartments. Thus certain hot-air stoves and ventilating fireplaces are forms of heating apparatus, but in addition both steam and hot water are used as warming mediums.

In factories and establishments where high-pressured steam is employed, the exhaust steam from the engines is in many cases passed through a series of tubes and used for heating. It is also economical and convenient to convey steam under pressure direct from the boilers through tubes, and, of course, in the latter case the amount of heat given off is very much greater. In such a case, pipes of small dimensions suffice for heating, and the size and amount of piping must be arranged with regard to the space to be heated, and the average pressure or heat at which it may be convenient to use the steam. Where the steam has to be specially raised it is generally preferable to use hot water in pipes.



Heating by water is carried out on two different systems; 1st, the ordinary or low-pressure system; and 2d, by Perkins' high-pressure system. In the low-pressure system the heat of the water never exceeds boiling point, and the principle is that by which hot water is conveyed to the various floors of an ordinary dwelling. The coils of pipe for heating ought to be arranged so that the incoming air passes over and is heated by them. The sole objection to the low-pressure system is the size and extent of the coils of piping necessary for adequately heating apartments of any considerable size. This objection is obviated in the high-pressure apparatus of Perkins, which consists of coils of pipe hermetically sealed, in which the water, superheated from 300 to 350° F., circulates with great rapidity. The pipes in this system are not more than an inch in circumference, made of malleable iron, and of great strength. There is greater danger of fire with high-pressure pipes, and leakage at any joint may occasion serious scalds or burns.

For manufacturing purposes very highly heated apartments are sometimes required, and among the devices employed to raise and maintain a high heat may be mentioned the use of Root's blower, or some similar device, which, passing a large body of air over an enormous coil of steam-heated pipes, raises and maintains a high temperature. A proportion of moisture may be added to this heat by injecting steam with the heated air.

Ventilation consists in the removal of impure air from an apartment, and in replacing that withdrawn with pure respirable air. As the structure of modern dwellings has improved and domestic conveniences and comforts increased, in proportion has grown the necessity for devising a sufficient means of securing ventilation, and though the problems connected with the subject appear to be simple, no method of ventilation has yet been devised which meets the necessities in every case, while the confidently touted nostrums of quacks are unusually numerous. The means by which the air of any apartment is vitiated are respiration, the products of combustion in artificial lighting, and the effluvia from the uncleanness of the apartment or the bodies within it. According to the purpose to which any apartment is devoted the means of ventilation must be proportionately modified. Thus in hospitals very special attention must be given to ventilation, and for theatres and other places where large bodies of people are closely packed together under artificial illumination the most complete system of ventilation is essential. The air in such places requires to be changed much more frequently than in any ordinary overcrowded apartment, and as the necessary rapidity of change increases, so also increase the difficulties of safe and comfortable ventilation.

The motion of any body of air is determined by a difference of pressure between it and that of the air surrounding it. Such a difference of pressure may result from heating the air, whereby it is expanded and tends to rise; or it may be due to the winds and external currents of air; or it may be artificially produced by suction or propulsion. Each of these causes is taken advantage of in the ventilation of rooms and halls. In all applications of ventilating agencies the points to consider are the means of admitting fresh air and of allowing the vitiated air to escape. Air must not only be introduced in sufficient quantities to maintain a healthy atmosphere, but it must also be introduced in a gentle, even, and imperceptible manner, draughts or felt currents of cold air being as dangerous as impure air.

In ordinary dwelling-houses heated by grates, the open fire usually exerts sufficient suction to renew the air as frequently as necessary, and the opening of doors and chinks of windows affords ample and properly-extended openings for the renewal of the air withdrawn by the fire. Where open fires are not used, the burning of gas jets under the orifice of ventilating shafts or tubes is a means of producing an outward current of air. The sun-lights in public buildings and the central chandeliers in theatres are thus utilised. The same principle is also applied in the ventilation of coal-mines, where an upward current is secured by the burning of large fires at the bottom of the upcast shaft. The ventilating power of external wind-currents is of course strong in proportion to the strength of the wind. Among the various forms of external ventilator designed to extract air by means of the wind may be mentioned the simple tube with a wide opening or cowl, which turns away from the wind; the archimedean ventilator which turns with the wind, and thereby rotates an exhausting screw within itself; simple louvres having a revolving fan within them; and the air-pump ventilator, the segments of which are arranged so as to direct the wind past the ventilating slit (fig. 3), and thus exert an extracting power while blowing from any direction. A study of almost any roof or set of chimney-pots will show how numerous and varied are the devices for keeping up a current of air in a uniform direction, and the prevalence of smoky chimneys is a practical commentary on their efficiency.

Fig. 3.—Ground Plan of Air Pump Ventilator.

The ventilation of the English Houses of Parliament may be taken as an example of a system successfully carried out on the best principles, for halls in which the necessities of ventilation vary enormously from time to time. The air is admitted into the lower part of the building by louvres, and there is an arrangement by which it can be laden with moisture, cold or hot, according to the season. It passes on to a series of immense steam-boilers, the number of which, and consequently the extent of heating surface, varies with the required temperature. These are placed under the central hall, and the heated air passing on from them is sifted through gauze to intercept particles, and thereafter admitted into the two houses, &c., through gratings in the floor covered by matting. The quantity of air to be admitted is regulated with the utmost ease by brattice-cloths placed over the mouth of the channel which leads the air from the heating boilers. The vitiated air is extracted by the suction of a large fire at the base of a central flue with which the two chambers are connected, and the gas at night being placed in the ceiling also aids in the extraction of the heated and vitiated gases.

The propulsion or suction of air into any space by mechanical agency—*e.g.*, by the use of rotating fans, or any form of blowing engine—has the great advantage of being in all circumstances under the most perfect control. It is, however, expensive in operation, and except in circumstances of special necessity is not put in operation. The punkah, used in India for creating a current of air within rooms, may be regarded as a form of mechanical ventilator, and indeed in a restricted sense the ordinary hand-fan of the ladies is similar in its purpose.

The artificial production and maintenance of a cold atmosphere has now become a most important problem in connection with the transport and preservation of meat in a fresh condition. See PRESERVED FOOD.

War'minster ('the monastery near the weir'), an old town of England, in Wiltshire, on the W. border of Salisbury Plain, and 19 miles W. of Salisbury by the Great Western Railway. The church, dedicated to St. Denis, has a tomb of Edward III.'s time; the St. Lawrence proprietary chapel was founded under Edward I. and rebuilt in 1725. There are several interesting antiquities, including the 'King's Barrow.' The making of broadcloth, for which W. was once famous, has long since ceased, but there is considerable local trade. Pop. (1871) 5786. Four miles S. is Longleat House, the seat of the Marquis of Bath.

War'-Office, one of the chief departments of Government presided over by the Secretary of State for War, who is assisted by a Permanent and a Parliamentary Under-Secretary of State. The W. O. is subdivided into three departments—military, ordnance, and financial, under the respective control of the commander-in-chief, the surveyor-general of the ordnance, and the financial secretary. The first officer has the supervision of the *personnel* of the army and all matters affecting its efficiency; the second deals with supply of all kinds, transports, &c.; the third with pay, audit, and kindred affairs.

W. O. Regulations embrace warrants and orders issued by the Secretary of State for War for the guidance and instruction of the various branches of the service. They are communicated to regiments and departments by circulars issued through the Horse Guards.

Warp is the longitudinal threads or yarn in any woven fabric. See WEAVING.

Warp'ing, in agriculture, is a process for adding to and enriching the soil by means of detritus carried down by rivers, or borne inland by the flowing tide. The operation, which consists in inclosing a body or sheet of water till the sediment it holds in suspension has deposited, can only be carried out on flat low-lying tracts which may be readily submerged. It is analogous to the natural process of fertilisation effected in Egypt by the Nilotic floods, and although little practised in the United Kingdom, it is of importance near the mouths of many European rivers.

Warr'andice, in Scotch law, is an obligation by which the party conveying a subject or right is bound to indemnify the grantee, disponee, or receiver of the right, in case of eviction, or in case of real burdens having been created over the subject before the date of conveyance. W. is *personal*, or *real*. The former binds the grantee and his heirs personally. By the latter, real estate is conveyed in security of the guarantee.

Warr'ant of Arrest' is usually issued on application to a justice of the peace. It should set forth the time, place, and cause of making. It should be directed to the peace-officer, requiring him to bring the accused person before a justice of the county, or before the justice who grants the warrant. The warrant in the latter case is called a *special* warrant. A warrant from the Queen's Bench division has force over all England, but the warrant of a justice of one county cannot be executed in another till signed by a justice of that other county. Some legal officers, justices, sheriffs, &c., may arrest without a warrant.

Warr'ant of Attor'ney. See ATTORNEY, WARRANT OF.

Warr'anty of Goods. In English law, if an *express* warranty proves false, the buyer is entitled to return the goods or to receive compensation, but a *general* warranty does not guarantee against obvious defects. See FAULT (in law).

Warr'en, Henry, an English artist, was born in London 24th September 1798, studied sculpture under Nollekens along with Bonomi and Gibson. After practising modelling at the British Museum, he became a student at the Academy in 1818, devoting himself ardently to painting in water-colours. Among his chief works are 'The Happy Valley,' 'Rebecca at the Well,' 'Christ and the Woman of Samaria,' 'The Death of the First-born,' 'The Dying Camel in the Desert,' 'The Crusader's First Sight of Jerusalem,' and 'First Sunset seen by our First Parents.' In 1835 he became a member of the Society of Painters in Water-Colours, of which, in the reorganised form as the Institute, he was president for thirty years. He has written *Artistic Anatomy* and *Water-Colour Painting*, both popular works.

Warr'en, Samuel, English novelist and lawyer, was born in Denbighshire, 23d May 1807, studied at Edinburgh for the medical profession, but afterwards went to London and qualified as a lawyer. He was called to the bar at the Inner Temple in 1837, made Queen's Counsel in 1851, and appointed Recorder of Hull in 1852. The following year brought him the degree of D.C.L. from Oxford; in 1856 and 1857 he was elected a member of Parliament; and in 1859 he was appointed by Lord Chelmsford a Master in Lunacy. He resigned the recordership of Hull in 1874, and died 29th July 1877. W.'s best achievements in fiction were *Diary of a Late Physician* (Lond. and Edin. 1832, 2 vols.), and *Ten Thousand a Year* (Lond. and Edin. 1841, 3 vols.); and in professional literature, *Popular and Practical Introduction to Law Studies* (Lond. 1835; new ed., entirely remodelled, &c., Lond. 1845); and *Blackstone Systematically Abridged* (Lond. 1857). As a novelist W. enjoyed an amazing success, which was not confined to England, but extended to America and the Continent. He possessed genuine humour, but of the kind which is hardly to be distinguished from extravagance and caricature. 'Tittlebat Titmouse' in *Ten Thousand a Year* bids fair to live long in the popular memory as the embodiment of a 'cad' blossoming into a 'swell.' Of W.'s lesser productions it is enough to note *The Lily and the Bee* (Lond. 1851), a strange rhapsodical poem on the Great Exhibition of 1851; *Now and Then* (Lond. 1847), a novel of religious tendency; and *Moral and Intellectual Development of the Age* (Lond. 1854). A collected edition of his literary works was published in 5 volumes (Lond. 1853-54), having been preceded by a German edition by Tauchnitz (1843-48).

Warr'ington, an old town of Lancashire, on the right bank of the Mersey, 20 miles E. of Liverpool by rail. It has a noble church, with a high steeple, which was restored at a cost of £14,000 in 1863, and five new churches have been lately built; the last, St. Barnabas, in 1879. There are many quaint timber-houses, and among the modern buildings are the town-hall (1862), the post-office (1876), and an hospital, erected (1876) at a cost of £7000. A good library of 2000 volumes was gifted to the town in 1875. Wire-drawing is a leading industry, and the manufactures comprise wire-work, files, edge-tools, pins, heavy leather goods, fustians, corduroys, twills, soap, glass, &c. W. is celebrated for its ale. The river is here crossed by a bridge, and the town is approachable by vessels of 100 tons. In 1877 the customs revenues amounted to £11,252. W. sends one member to Parliament, and publishes three newspapers. Pop. (1871) 33,053.

Warrnambool', a seaport of Victoria, Australia, 170 miles S.W. of Melbourne. It has a safe harbour, and being the centre of a rich agricultural and pastoral district, exports largely potatoes, wheat, wool, and preserved meat. Pop. (1876) 4600.

War'saw (Pol. *Warszawa*, 'the fortified place,' Ger. *Warschau*, Fr. *Varsovie*), the capital formerly of Poland, now of the government of W. in Russia, lies in the form of a half-moon along the left bank of the Vistula, 676 miles S.W. of St. Petersburg by rail. It consists of an old and a new town and several suburbs, the principal, Praga, on the opposite side of the river, joined to the city by two iron bridges, the one for public traffic 1663 feet in length, the other—a railway bridge —built in 1873. W. is strongly fortified, girt with walls and ditches, and commanded by the impregnable Alexander citadel, built 1832-35. Within its walls are an extensive parade-ground, 12 handsome squares, several avenues planted with poplars and chestnuts—the principal, the Jerosimer and Ujasdower—and more than 200 streets, of which the finest are the Lesch-no, Miodowa, Dluga, Nowy Swiat, Electoralna, Mazowiecka, and Czysta streets, and the Krakowski Przed-

miast, with an equestrian statue of Jozef Poniatowski, one of the masterpieces of Thorwaldsen. Opposite Praga, from terraced gardens along the bank of the river, rises the grandest edifice in W., the former royal castle, a two-storied square, built by Sigismund III. and completed by Stanislaus Poniatowski, containing the Polish archives and a rich collection of pictures and statues. Other buildings are the Saxon palace, the residence of Augustus II. and Augustus III., with a fine garden; the government buildings, formerly the Radziwill Palace; the war-minister's palace, formerly that of the primate; the town-house, formerly the palace of Prince Jablonowski, newly built after the fire of 1863; the university, formerly the residence of Jan Kazimierz; and the more than 100 other palaces of the old Polish nobility. Among the 85 churches of W. the finest are the Catholic cathedral of St. John, founded in 1360, connected with the castle by a corridor, and containing Turkish spoils of John III. Sobieski, and a fine altarpiece by Palma Nova; the Greek cathedral, completed in 1842; the Lutheran church, in the centre of the city, one of its loftiest buildings; the Reformed church, built in 1623 by Sigismund III.; the churches of the Holy Cross, Borromeo, and St. Alexander; and a new synagogue, opened September 1878. The educational institutions are the university, founded in 1816, abolished in 1832, but restored in 1864, with a library of 200,000 vols. and a fine botanical garden (450 students); 6 Gymnasia, with 2364 students; a Realschule, with 388 pupils; the Institute of St. Mary, a ladies' school, with 247 pupils; 4 Gymnasium for females, with 1126 pupils; a normal seminary, with 59 students; 147 private schools, with 11,037 pupils; a veterinary school, with 92 students; a school of design, with 258 students; an institute for the deaf and dumb and for the blind, with 222 pupils; a commercial school, with 300 pupils; a Sunday commercial school, with 581 pupils; and several schools for artisans, with an aggregate attendance of 4604. The chief benevolent society has an annual income of £12,650. In 1877 the hospitals had 37,330 patients, and the foundling hospital in 1873 4000 children. W. is the centre of the industrial and commercial activity of Poland. It has nearly 300 factories, and produces annually goods to the value of nearly £3,000,000; consisting chiefly of tobacco, distilled products, beer, milled products, oil, waggons, &c., musical instruments, machinery, gold- and silver-plated articles, and other metal wares, chemicals, soap, and leather. Pop. (1877) 315,199 (185,811 Catholic, 104,160 Jews, 16,926 Protestants, 8796 Greek Catholics), besides a strong garrison (before the Turkish war 21,933 men). The history of W. is noticed under POLAND.

Wart'burg, War of the, was a poetic contest between the most famous minstrels of the day, said to have taken place at the castle of Wartburg, near the town of Eisenach, in 1206 or 1207. The strife is described in a celebrated poem by an unknown author, of date about 1290, and written in Middle High German. The poem consists of two parts. In the first we are told how Heinrich von Ofterdingen sings the praises of Duke Leopold of Austria, whilst Walther von der Vogelweide extols the deeds of the Landgraf of Thüringia. In this strife Walther is victorious. The second part (of much later origin) tells how the magician Klingsor, from Hungary, comes at the call of the discomfited minstrel. A sharp trial of wit ensues between the new-comer and Wolfram von Eschenbach, in which the latter triumphs. The fact that some sort of a poetic contest did probably take place at Castle Wartburg about the time indicated does not at all prove the authenticity of the alleged account, of which the incidents are pure fiction. The best edition, with translation into modern German, is by Simrock (Stutt. 1858). See also Lucas, *Ueber den Krieg von Wartburg* (Königsb. 1838); Plötz, *Ueber den Sängerkrieg auf der Wartburg* (Weim. 1851). The story is also poetically treated in Wagner's 'Tannhäuser.'

War'the, the principal tributary of the Oder, rises near Kromolov, in Poland, flows N., at Kolo turns to the W., at Schrimm again to the N., at Obornik to the W., and at the influx of the Obra finally to the N., at the influx of the Netze enters on the Wartebruch, a swampy tract 46 miles long by 9 wide, and joins the Oder at Küstrin, where it is 640 feet broad. Its tributaries are, from the right the Netze and Küddow, from the left the Prosna and Obra. Its total length is 487 miles, of which 222 miles belong to Prussia.

Wart'-Hog (*Phacochærus Œgypticus*), a species of *Suidæ*, or swine, found in Africa, and known at the Cape of Good Hope as the 'Vlacke Vark' and 'Engalla.' It attains a length of 4 feet, and is notable for its large tusks. Its colour is a dull or blackish grey. The head and fore parts are disproportionately developed as compared with the hinder parts, and the appearance of the animal is highly grotesque. The W.-H. is by no means destitute of courage, and the tusks constitute weapons of attack of no mean kind. The name is derived from the presence on the cheeks of warty growths or excrescences. An allied species is the *P. Œliani* or Abyssinian wild boar. An allied genus, *Potamochærus* or *Cheiropotamus*, includes the Bosch Vark (*C. Africanus*) or Bush-hog of S. Africa and the *C.* or *P. pencillatus* of W. Africa.

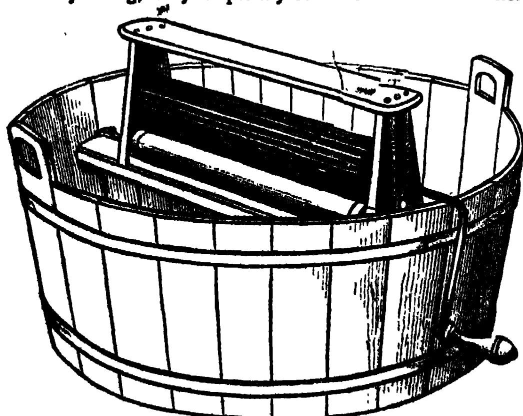
War'ton, Thomas, an English author, was born in 1728 at Basingstoke, where his father was vicar. In 1743 he entered Trinity College, Oxford, and in 1751 obtained a fellowship. From 1757 to 1767 he was professor of poetry, an office which his father had held before him (1718-28). In 1771 he obtained the living of Keddington in Oxfordshire, and in 1785 he was appointed Camden professor of ancient history and poet-laureate, both of which appointments he held till his death, May 21, 1790. W. began his literary career while still an undergraduate by a poem, *The Pleasures of Memory;* but he owes his importance to his critical and historical labours. His great work, *The History of English Poetry from the Close of the Eleventh Century to the Commencement of the Eighteenth Century* (vol. i. 1774, vol. ii. 1778, vol. iii. 1781; new ed. by Hazlitt, 3 vols. 1870), in spite of the multiplex activity of subsequent investigators in the same department, remains one of the most valuable of literary surveys. Among W.'s minor undertakings was an edition of Theocritus (1770), and some other work in the same department; *Observations on the Faerie Queene of Spenser* (Lond. 1754; new ed. 1762), a *Life of Sir Thomas Pope* (Lond. 1772), and an edition of Milton's *Poems upon Several Occasions* (Lond. 1785). He was one of the first of Englishmen to take a genuine interest in the old churches and castles of his native land, and at one time he intended to write a history of Gothic architecture in England. His observations critical and historical are still preserved in MSS., and a brief description of their contents will be found in the *Cornhill Magazine*, 1865, vol. xi. W. was a kindly-tempered blithe-hearted man, and most of his friends must have felt what his great posthumous friend Christopher North expressed, that he was 'one of the finest fellows that ever breathed.' A fondness for sights of all kinds was a noticeable feature in his character. See Life of T. W. prefixed to Richard Mant's edition of his Poems (2 vols. Lond. 1802).—**Joseph W.,** brother of the preceding, was born in 1722 at Dunsford in Surrey. From Winchester he proceeded in 1740 to Oriel College, Oxford, where in 1744 he took his degree of B.A. About the same time he was ordained curate at Basingstoke, and in 1748 he received from the Duke of Bolton the rectory of Winslade, which enabled him to marry. We soon after find him abroad with the duke, and, if the old biographer does not belie him, on no very honourable mission: the duchess was evidently dying, the duke had a mistress, and W. was to be in readiness to make the mistress a wife on the earliest opportunity. In 1754 he obtained the rectory of Tunworth; in 1755 he was appointed second master of Winchester School, and in 1766 head-master. He became a prebendary of St. Paul's (1782) and of Winchester (1788), and in 1793 resigned his post at Winchester, retiring to his rectory at Wickham. He died Feb. 23, 1800. Joseph W. has left no great work like his brother's *History of English Poetry*, but he contributed ably to the critical literature of the day. His *Essay on the Genius and Writings of Pope* (1st vol. 1756, 2d 1782) did good service by calling in question the canon of the prevailing school, which made the 'correctness' of a poet's style the measure of his greatness. Spenser, he maintained, was worthier than Pope of the title of poet. His minor productions comprise a translation of Virgil's Eclogues and Georgics, with essays on pastoral, didactic, and epic poetry, and contributions to the *Gentleman's Magazine, Dodsley's Museum*, and *The Adventurer*. He edited Pope's works, and left an unfinished edition of Dryden, afterwards completed by his son, John W. See Rev. John Woll, *Biographical Memoirs of J. W.* (Lond. 1806).

Warts, or **Verru'cæ,** are collections of hypertrophied papillæ covered with epithelium, and sometimes hardened by friction

and exposure. The most common situation of ordinary W. is the hands of children, and occasionally other parts of the body, as the eyelids and face. The *branching wart*, or *verruca digitata*, forms sometimes on the scalp of women. Sub-ungual W. form below and at the side of the nails, and from their position cause much pain. *Verruca confluens* is formed of a crop of small W. generally on the back of the hand, the arm, the neck, or the thorax. In such cases the skin may resemble coarse plush, and great irritation may be caused. Venereal W. are due to the irritation of discharges retained in contact with the skin or mucous membrane, and are frequently associated with condylomata consisting of hypertrophied skin. They often spread over a large surface and attain a considerable size. *Verrucæ necrogenicæ* are W. due to the irritation of morbid fluids, and are occasionally found on the hands of morbid anatomists. The causes of the common W. are unknown. They appear and disappear in a capricious manner, and usually they are a mere disfigurement. W. may be removed by thoroughly saturating them with nitric acid, the acid nitrate of mercury, glacial acetic acid, perchloride of iron, or by repeated applications of nitrate of silver.

War'wick ('the fortified place'), the county town of Warwickshire, 107¾ miles N.W. of London by rail, is chiefly situated on the southern shore of the 'sleepy, willowy Avon.' On the opposite bank, crowning a solid rock, stands W. Castle, rearing its towers, Cæsar's (147 feet) and Guy's (128 feet), above the cedars of the surrounding park, and storing within its state apartments rich tapestries, pictures by Rembrandt, Van Dyck, and Rubens, collections of armour and other rarities, among them the famous 'W. vase.' The restoration of its hall, gutted by fire in 1871, was completed (1876) at a cost of some £18,000. St. Mary's Church, mainly rebuilt in 1704, retains its old Perpendicular choir and Beauchamp chapel (1370–91), with the tombs of four centuries of W.'s earls; over the E. Gate is an ancient chapel, until recently used as a free school; and Leicester's Hospital, founded for twelve brethren in 1571, is a quaint quadrangular building, with a Gothic chapel surmounting the W. Gate, a mighty kitchen, and vaulted hall, profusely adorned with its founder's cognisance, the Bear and Ragged Staff. The town itself, having suffered much from fire, is generally modern, among the recent buildings being a Roman Catholic church (1860), the county hall and courts, a domed market-house, the county gaol (1860), a theatre, and antiquarian museum; and new waterworks were constructed (1876) at a cost of nearly £25,000. Ironfounding, brewing, and brickmaking are carried on, but agricultural produce forms the staple of the trade of W., which publishes one weekly newspaper and returns two members to Parliament. Pop. (1871) 10,986. Traditionally connected with King Cymbeline, its reputed founder in 1 A.D., and with Guy of Warwick, the vanquisher of the giant Colbrand, W. figures in *Domesday* with 261 houses, having earlier been sacked by Danes, but restored by Ethelfleda, Ælfred's daughter, in 914. William of Newburgh, a follower of the Conqueror, replaced her fortress by the castle, which Stephen surrendered to Prince Henry (1153), which was Edward IV.'s prison (1469), and which has been visited by many of England's kings. See vol. i. of Hawthorne's *Our Old Home* (Lond. 1863).

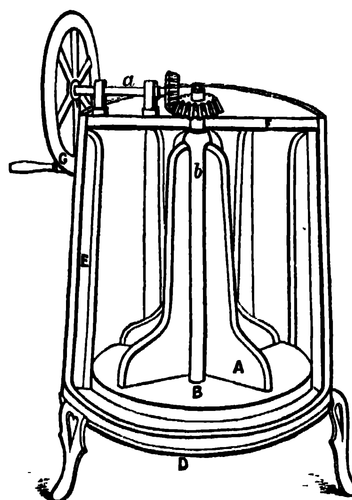
War'wick, Richard Neville, Earl of, 'the King-maker,' born about 1420, was the eldest son of the Earl of Salisbury, and by his marriage with the heiress of the Beauchamps himself became Earl of Warwick (1449). In the Yorkist victory of St. Albans (1455), the opening action of the Wars of the Roses, he fought on the winning side, and three years later sharing in the reconciliation between the hostile parties, was appointed lord-deputy of Calais and admiral of the fleet. As such he gained a splendid success over the Spaniards, but a quarrel between his followers and the king's led to charges of disloyalty, which he justified by taking the field at Ludlow with his cousin the Duke of York (1459). On the failure of that attempt he again with the Earls of Salisbury and March withdrew to Calais, a town devoted to his cause, and thence in the following summer recrossed to Kent, and, mastering London and capturing Henry VI. (q. v.) at Northampton, brought about the compromise by which Henry was to reign for life but acknowledge York for his successor. Margaret of Anjou would not thus tamely surrender the rights of her son, and first routing and slaying York and Salisbury at Wakefield advanced to St. Albans, where a second battle ended in W.'s defeat. W., however, joined the young Earl of March (now Duke of York), and striking with him boldly on London, placed him upon the throne as Edward IV. (q. v.), then chasing the Lancastrians back to Yorkshire, almost annihilated them on the bloody field of Towton, 29th March 1461. Possessed of immense domains and princely wealth, with one brother rewarded for his crowning victory at Hexham by the earldom of Northumberland, another made Primate and Lord Chancellor, W. indeed seemed able now, in Shakespeare's words, 'to do and undo, as him pleased best.' Edward's marriage, however, to Elizabeth Woodville pleased him not, especially as he was then negotiating for the king's alliance to Bona of Savoy; neither did the marriage of Edward's sister to Charles of Burgundy, the Earl's great foe. In retaliation W. bestowed his daughter on the Duke of Clarence, and after seizing on Edward's person, executing the queen's father and brother, and seeming to accept a pardon, involved himself in the insurrection of Sir Robert Welles (1470) for making Clarence king. Its failure drove him once more to France, where, through the mediation of Louis XI., W. engaged to restore the crown to Henry VI., and Margaret to wed her son to W.'s daughter Anne. His landing in Devonshire came like a thunderclap to Edward IV., who from the North, where he was busy quelling a revolt, escaped to Burgundy, leaving W. master of the kingdom. The triumph was brief, for when Edward returned in six months' time, W. found himself treated as he had treated others, and after fruitless overtures for a fresh desertion, he with his brother was routed and slain at Barnet, 14th April 1471. Of this 'Last of the Barons,' Mr. Gairdner says that 'his policy throughout appears to have been selfish and treacherous, and his removal was an unquestionable blessing to his country.' See Gairdner's *Houses of York and Lancaster* (Lond. 1874).



War'wickshire, a midland county of England, is bounded N.E. by Leicestershire, S.E. by Northamptonshire and Oxfordshire, W. by Gloucestershire and Worcestershire, and N.W. by Staffordshire. Area, 566,458 acres; pop. (1871) 634,189. The southern and larger portion of the county is traversed for 57 miles by the Avon (q. v.), and so belongs to the Severn basin; in the northern, formerly covered by the Forest of Arden, the Tame, an affluent of the Trent, rises and takes its course for 20 miles. Valleys alternate with gently-sloping uplands, and geologically W. mainly belongs to the Secondary formation, having one coal-field which yielded (1878) 930,850 tons, while the output of iron (1875) was 97,456 tons. The soil is chiefly red and sandy loams or clay, and in 1878 there were 142,316 acres under corn crops, 63,681 under green crops, 66,312 under clover, sainfoin, and grasses in rotation, and (1872) 18,529 of woods. In the same year W. had 19,928 horses, 90,272 cattle, 347,427 sheep, and 43,262 pigs. The manufactures, of high importance, have been described under their centres, Birmingham and Coventry, the other chief places being Warwick, Leamington, Rugby, Kenilworth, and Stratford-on-Avon. The county returns four members to Parliament, and its gross rental amounted (1874) to £3,428,771, its poor-rate (1877) to £296,121, and the number of its paupers (1878) to 18,352.

Wash, an estuary on the E. coast of England, having Lincolnshire in its N.W. and Norfolk on its S.E. side. Its length is 22 miles, and its breadth about 15. The Lynn Deeps on the Norfolk side, and the Boston Deeps on the Lincolnshire side, afford anchorage to well-sized ships, but most of the estuary is very shallow. The Witham, Welland, and Ouse are the principal rivers which enter the W. See Miller and Skertchly, *The Fenland* (Wisbeach 1878).

Wash'ing. In this article notice is taken of laundry operations only; the processes of W. connected with wool-scouring and the bleaching and printing of linen and calico being dealt with under separate heads. The W. operations of domestic life are of importance on account of the amount of labour and expenditure connected with them, and of their social and hygienic influence. In the practice of a well-conducted laundry or domestic W. there are considerable variations, the possession or want of various machines and appliances to some extent modifying practice. The absolute essentials of all efficient W. are a supply of pure soft water, soap, soda, a washing-tub, a boiler, and an expert pair of hands. With these only, and with a proper open-air drying and bleaching place, a large proportion of domestic W. is done, and that in a most thorough manner. In localities where



the ordinary water supply is hard, it is desirable to impound rain water, than which nothing can be better for W. Hard water is not only wasteful of soap and time, but in no case can it produce the satisfactory results that are derived from the use of a soft, easily-lathered water. In preparing for W. a separation is first made between white articles (*i.e.*, bed, table, and body linen) and coloured articles and woollens. The white articles are rubbed slightly with soap at the stained spots, and placed in steep for a few hours in water to which a proportion of soda, with sometimes a little soap, has been added. In the actual operation of W. the articles are wrung out of the steep; a tub is then half filled with water as hot as can be comfortably borne by the hand; to this a proportion of boiled soap, sufficient to raise a lather on the water when it is agitated, is added. The smaller, finer, and comparatively clean articles are first washed with the view of economising soap, and thereafter the larger articles are taken in hand, soap being rubbed on as needed where obstinate stain-spots remain. Coloured articles, such as printed calicoes, &c., require very careful treatment to preserve the brightness of the dye, and keep it from running over and clouding the lighter parts of the pattern. They cannot be steeped; no soda is to be added to the water; the articles should be washed out as quickly as possible, rinsed through cold water, and immediately hung up to dry. Similarly, woollen and worsted articles should be washed through a hot solution of soap with as little rubbing and squeezing as possible, shaken out, and quickly dried. In the case of white articles, after W. a common practice is to boil them in a solution of soap, thereafter rinse them through cold water, in which they may remain for some time, and where they may advantageously be treated with a minute proportion of laundry blue. From this the articles are squeezed as dry as possible and hung out to dry thoroughly. When dry the articles are neatly folded up, bed and table linen is mangled, other non-woollen articles are ironed; shirts, collars, and similar objects for personal wear are starched and smooth-ironed; and there are various other ways of finishing small articles. A commendable practice is to expose the articles immediately after boiling on a W.-green to the bleaching influence of the sun, after which they are washed up and dried. As a substitute for such bleaching, a proportion of a clear solution of bleaching-powder may, with good effect, be added to the cold steep after boiling. The W.-powders so much vaunted by their sellers are simply powdered soda with more or less of bleaching-powder (chloride of lime) added.

As already stated, a variety of mechanical appliances are now in common use for facilitating the laborious operations connected with W., but many W. machines are very destructive of clothes. The simplest aid is the W.-board, which consists of a fluted hard-wood board, or sheet of corrugated zinc laid slantingly into the tub, and on which the washer rubs with both hands. It would be impossible here to give any idea of the endless mechanical contrivances that have been introduced to supersede manual labour in W. They for the most part depend on either rubbing or beating in action, and as they possess little power of yielding, they frequently strain and tear the articles.

People's Washing Machine.

The 'Peoples' W. Machine,' made by Macfarlane, of Albert Works, Glasgow, is very simple, and the cheapest of all mechanical washers. It washes by friction and pressure, and, as will be seen from the illustration, consists of two pressing and two crimping rollers fitted into a suitable frame, having the pressure supplied by spiral springs. These rollers work together, and act upon the clothes in the same manner as the knuckles in hand-W. The clothes are passed backward and forward between the rollers, and as they are being continuously saturated, the dirt is quickly loosened and carried off. One of the least objectionable of all machines is the 'Home Washer,' made by Taylor & Wilson, of Accrington, shown in accompanying fig. It is in form of a tub, made of staves, secured by galvanised iron hoops, and fitted internally with a series of upright breaks, shown at E. Across the top there is a strong wood cross bar F, and reaching from it to the bottom centre of the tub runs a shaft *b*. This shaft has a circular disc B attached to its lower end, and is provided with 4 radial fins A, of ogee form, the lower ends of which rest upon the disc or table. The central shaft is rotated or revolved by means of a set of mitre or cog wheels C, fixed to a wrought-iron shaft *a*, and moved by a crank G. By turning this crank the central shaft and its floats are rotated, thereby creating a violent commotion of the water; a series of counter currents are formed, which, forced by the action of these floats and breaks, passes through the fabric to be washed in every possible direction. W. machines are made of any size according to the necessities of the case, the larger ones being moved by steam. The clothes' wringer is a most desirable and useful instrument for squeezing water out of clothes. In consists of a pair of india-rubber rollers, mounted on iron spindles in a strong frame, and pressed against each other by a strong elliptic or other spring. In large establishments a hydro-extractor is used for drying, the effect of which is due to the centrifugal force developed by the extraordinarily rapid rotation of a circular basin with perforated sides into which the clothes are placed. For thoroughness, rapidity, and absence of all strain, no appliance can approach this apparatus, which has extensive application in other departments of industry as well as in domestic W.

Section of "Home Washer."

Wash'ing of Feet was a ceremony very generally practised in the primitive Church. The reason for it was threefold, or there seem to have been three kinds of it. (1) It was done in the case of travellers and guests as an act of Christian hospitality in imitation of time-honoured examples (*cf.* Gen. xviii. 4, xix. 2). (2) It was a practice for the Catechumens (q. v.), who had fasted and refrained from all ablutions during the whole time of Lent (q. v.), to bathe themselves, for decency's sake, previous to their baptism at Easter; and in some places this was changed into a ceremony of washing their feet by the bishop, as if it were an essential part of the rite of baptism, although, on the other hand, it was sometimes done after baptism just to prevent this

supposition. (3) A third kind of W. of F. was practised on a certain number of poor persons (generally twelve, the number of the disciples) on Maundy Thursday (q. v.) as a voluntary act of piety in imitation of the example and obedience to the command of Christ (John xiii. 1–15). This ceremony was kept up till comparatively recent times by many high dignitaries, and is still by the Pope.

Wash'ington, George, first President of the United States, was born 22d February 1732 at his father's house on the Potomac river, Westmoreland county, Virginia. His great-grandfather, John W., was an English royalist who emigrated to America during Cromwell's supremacy in England. Further back than this his ancestry cannot be satisfactorily traced. Some suppose the family to have belonged originally to the county of Durham, while others trace it to Sulgrave, Northamptonshire. W.'s father, Augustine W., was a wealthy landed proprietor. He was twice married, and had four children by his first wife, while W. was the eldest of a family of six by the second wife, Mary Ball, daughter of Colonel Ball, a Virginian gentleman of good station. He received little school education beyond the ordinary rudiments, the only subject which he prosecuted more deeply being mathematics. Nor does it appear that he received much culture from his home life, his parents being by no means above the average of their station in attainments, though they seem to have possessed in a great measure the strength of character and unswerving probity which were afterwards so splendidly developed in their son. Apart from certain apocryphal anecdotes, abundant evidence exists of the careful moral training which he received in his childhood. In all the athletic sports, too, of the rather rough colonial life around him, he was thoroughly proficient. His spare, well-knit frame combined considerable muscular strength with great capacity for endurance of fatigue; and these physical qualifications, along with his turn for mathematical work, led him to adopt the profession of a land-surveyor, in all new countries an important and lucrative business. It is probable, however, that but for his mother's opposition he would have chosen a naval career, a midshipman's warrant having at one time actually been obtained for him. He was sixteen years of age when he began active work as a land-surveyor on the great estate of Lord Fairfax in the Shenandoah Valley, and the laborious and even dangerous experience which this occupation involved stood him in excellent stead in after years. The colonial militia being organised for service against France in 1751, W., though only nineteen, was appointed adjutant with the rank of major, but did not then take part in any active service. In the same year he accompanied his elder half-brother, Captain Lawrence W., in a voyage to the Barbadoes. This was the only occasion on which W. left the American continent. Lawrence W., who had served under Admiral Vernon in the expedition against Carthagena in 1740, had inherited from his father an estate, which he called, in honour of his old commander, 'Mount Vernon.' Dying in 1752, he left all his property to an infant daughter, who also died shortly afterwards. The estate of Mount Vernon then came into the hands of W. himself, and was ever afterwards his family residence. About this time alarm was excited in the colonies by a scheme of the French government for connecting their possessions in Canada and Louisiana by a chain of forts along the Ohio Valley, which would effectually check the westward spread of English colonisation. Dinwiddie, the governor of Virginia, chose W. to act as the agent of the English Government, and confer with the French commander in the Ohio district. The journey was a dangerous and tedious one, and produced no results. In the next year (1754) W. was placed in command of a small military expedition destined to hold the French in check. He commenced the construction of a fort in a strong position at the junction of the Alleghany and Monongahela rivers, where the city of Pittsburg now stands. At first he gained a slight advantage over the French, but his force was too small to cope with them for any length of time, and he was ultimately forced to capitulate, on most favourable terms however, at a place called Fort Necessity, where he had entrenched himself. In spite of the unfortunate result of this expedition, it added to W.'s credit in the colony. When, in 1755, General Braddock was placed at the head of a considerable force sent to operate against the French in the same region, W. joined him as a volunteer, and was present at the disastrous massacre on the Monongahela, where Braddock and most of his army were killed, and where W. himself was the only officer unwounded, though he 'had four bullets through his coat, and two horses shot under him.' A force of 2000 men was now raised for the protection of the frontier, and the chief command was conferred upon W., who fixed his headquarters at Winchester, and for three years performed with credit the arduous and harassing duties of his post. In 1759 he married Mrs. Martha Custis, a wealthy widow, of the same age as himself however, and owning a property contiguous to his own. Resigning his commission about the same time, he devoted himself to the cultivation of his own and his wife's properties, which he conducted with great success. His habits both of life and of business were rigidly methodical, and his accounts and farm reports remain to this day as monuments of his business capacity. His summers were for the most part spent at Mount Vernon, but in winter his duties as a member of the Provincial Assembly called him frequently to Williamsburg. This peaceful and monotonous routine of life continued until the outbreak of the Revolution. By family tradition, by habit of mind, and by his former military life, W. was inclined to the staunchest loyalty, and he seems to have been most unwilling to recognise the necessity of a separation from the mother country. His love of liberty and sense of justice were, however, too strong to render it doubtful which side he would adopt when matters came to a crisis. This they did at Lexington and Concord Bridge on the 19th April 1775. On the 15th of the following June the Continental Congress unanimously chose W. as commander-in-chief of the Continental army, and he accepted the task, far from joyfully, indeed, but with a stern resolve to do his duty in the defence of the endangered liberties of his country. On July 3d he took command at Cambridge of the army besieging Boston, and for the next nine months he conducted the siege, until its triumphant conclusion, 17th March 1776. Not so successful were his next operations in New York and New Jersey. Obliged to witness the defeat of General Putman at Brooklyn from the opposite shore of the East River, driven from New York, and forced to retreat step by step through the Jerseys with a rapidly-diminishing army, he barely retrieved his fortunes by the brilliant skirmish of Trenton, and the subsequent attack upon Cornwallis's army at Princeton. The reverses of Brandywine and Germantown and the British occupation of Philadelphia followed, and during the terrible winter at Valley Forge the fortunes of the Continental cause seemed to have reached the lowest ebb. Yet the British successes had been more apparent than real, and W.'s 'policy of delay,' grounded on the knowledge that, while the king's troops might overrun the country, they could not conquer it, was in reality by far the wisest he could have adopted. The difficulties with which he had at this time to contend were such as to demand for their encounter a fortitude amounting to heroism. His army lacked both clothing and supplies, his treasury was empty, or filled with money worthless through depreciation, a spirit of mutiny was abroad among his troops, the short-sighted meddling of the Congress hampered and galled him, and to crown all, his apparent ill-success was contrasted in the popular mind with the brilliant exploit of Gates at Saratoga, very much to his disadvantage. Still he remained master of the situation. Untiringly active, unmoved by jealousy or petulance, rendered fearless of envy and slander by the proud purity of his motives and conduct, he held on his way with an unswerving confidence such as only the rarest courage can inspire. Gradually matters brightened, and the wisdom of his course was proved. The surrender of Cornwallis at Yorktown, 17th October 1781, crushed the hopes of the British, and the war barely lingered on until the evacuation of New York, 25th November 1783. On the 23d December of the same year W. resigned his command. He at once retired to Mount Vernon and resumed his beloved country occupations, trusting that his public life was at an end. But this was not to be. It soon became evident that a strictly defined and formulated constitution was necessary to prevent the newly liberated country from falling into anarchy. With the politic caution which places him as high among statesmen as he stands among patriots, W. gradually led up to the idea of a Convention for the arrangement of a form of government. The Convention met at Philadelphia in May 1787, and under his presidency it drew up the present United States' Constitution. Unanimously elected by his grateful countrymen to the Presidency of the Republic, W. filled that office for two terms (1789–

1796) with a moderation and sagacity which were perhaps as valuable to the new state as his former military services. He was, in fact, the one man in the country to whom could be entrusted the delicate task of consolidating and establishing the executive machinery. Though privately inclined to what would now be called Republican views, he held the balance between the conflicting parties with absolute impartiality, and did not gratify his longing for rest and privacy until he felt that his part of the work was done, and that he could safely leave its continuance in other hands. His farewell address was issued on the 17th September 1796, when he withdrew to Mount Vernon and resumed the simple occupations of his country life. Scarcely a year had elapsed when his repose seemed likely to be disturbed by a war with France, in preparation for which he was again appointed commander-in-chief of the United States troops. The immediate danger blew over, however, and for two more years he enjoyed the quiet of his favourite home. But on Thursday the 12th December 1799 he was caught in a heavy storm of snow and sleet, and early on Saturday morning he became seriously ill. 'Acute laryngitis' declared itself, and after much suffering he died on the evening of Saturday, December 14th. He had no children, and his property was left to step-children, nephews, and nieces. At the time of his death he owned 124 slaves on his own estate, and probably nearly as many on his wife's. His will directed that they should all be enfranchised on the death of his wife, which occurred three years after his own. He had determined as early as 1786 never to purchase another slave.

W. was one of the few great men of history whose character comes out spotless from the most microscopic examination. To his great qualities as a soldier and a statesman he added all the virtues of private life—integrity and benevolence, piety without narrowness, a genuine if somewhat stiff and formal courtesy. In manners and habits of thought he seems to have been in the best sense 'a gentleman of the old school.' But his great claim to admiration lies in the almost unexampled modesty and simplicity of his character. The successful leader of one of the most wonderful wars on record, in which a handful of disunited colonies shook off the yoke of a great empire, the chief founder of a nation which had already given sure proof of its coming greatness, he not only resisted every temptation to abuse in the slightest degree the advantages of his position, but he even appeared unconscious of the magnitude of the work he had performed. He laboured for his country with a singleness of purpose and absence of self-seeking as rare as they are admirable, and, his task done, he returned simply and with no ostentation to his duties as a private citizen. 'First in war, first in peace,' he deserved, if ever any-one did, to be 'first in the hearts of his countrymen.' Many lives of W. have been written, the best being Marshall's (Philadelph. 1805; abridged 1832), Washington Irving's (New York 1855-59), Everett's (New York 1861), and Jorrault's *G. W., d'après ses Mémoires et sa Correspondance* (Pa.. 1876), while the great storehouse for biographers is the collected *Writings of G. W.* by Jared Sparks (22 vols. Boston 1834-37). A volume of *W.-Crawford Letters* was published by C. W. Butterfield in 1877, and of *W.-Heath Letters* by the Massachusetts Historical Society in 1878.

Wash'ington Terr'itory, the most N.-westerly division of the United States, bounded N. by British Columbia, E. by Idaho, S. by Oregon, and W. by the Pacific Ocean. Area, 79,128 sq. miles; pop. (1870) 37,432, including 13,477 tribal Indians in the reservations, and 1760 other Indians and Chinese. W. T. is divided geographically into two great sections by the Cascade Mountains, which pass through the territory from N. to S., and present to the W. an almost unbroken range of from 5000 to 8000 feet, rising in Mount Rainier to 14,444 feet, in Mount Baker to 11,100, in Mount Adams to 9000, and St. Helen's to 9750. Stretching eastwards is a lofty plateau, dry and sterile, channelled by the fertile valleys of the Yakima, Methow, Okinapum, and other rivers. The Blue Mountains, the summits of this plateau, attain a height of 9000 feet, but sink to 5000 near the Walla Walla. The eastern and greater division of W. T. lies wholly in the Basin of the Columbia River, and is, with the exception of the barren Spokane plains, a pleasant, fertile, diversified country, with plenty of timber. The Columbia enters from British Columbia, receives the Clark just beyond the frontier, and flows in a southerly direction, being joined by the Spokane, Okinikane, Methow, Yakima, Snake River, and Walla Walla. On reaching the Oregon line it turns sharply to the W. and forms the boundary of the territory to the Pacific, a distance of 300 miles. In the western section of W. T., beyond the Cascades, there is a coast range, which extends in irregular masses from the Oregon shore to Cape Flattery, at Juan de Fuca Strait, where it terminates in bold, lofty headlands. The southern part of this range is low, but it has an elevation in Mount Olympus of 8150 feet. The Pacific coast is for the most part abrupt and unbroken; the only safe inlets are Shoalwater Bay and Gray's Harbour. Beyond Cape Flattery, however, the extensive inland sea of Puget's Sound has some of the finest roadsteads in the world. The sound has an area of 2000 sq. miles, and a coastline of 1600 miles, and among its best-known indentations are Bellingham Bay, Hood's Canal, and Admiralty Inlet. There are numerous islands in the sound, which receives many minor rivers. Throughout W. T. are scattered a large number of lakes of considerable size. The Cascade Mountains, and most of Eastern W. T., is of Metamorphic formation. In the N. this gives way to Eozoic, while in the W. the prevailing rocks are Tertiary and Cretaceous. Iron is widely distributed, gold has been found in the N.E., and bituminous coal is mined at various points on Puget's Sound. The forest trees of Western W. T. are unsurpassed in height or beauty except by the giant redwoods and sequoias of California. The red, white, and yellow pine, various firs, and the Oregon cedar, are from 175 to 350 feet high, and from 8 to 15 feet diameter. The deciduous trees are the maple, ash, laurel, alder, &c. Where water is abundant the crops are luxuriant, as much as 85 bushels of wheat being produced to the acre, the wheat weighing 62 lbs. to the bushel. In 1870 only 646,139 acres were farmed, and the crops comprised 217,043 bushels of wheat, 21,781 of Indian corn, 255,169 of oats, 55,787 of barley, 281,144 of potatoes, 15,790 pease and beans, 30,233 tons of hay, 6162 lbs. of hops (200,000 in 1875), 1682 lbs. of tobacco. There was also produced 162,713 lbs. of wool, 407,306 of butter, 17,465 of cheese, and 25,636 of honey. Fruit, flax, sugar, and beets are largely raised, and there is abundance of bunch-grass. The value of live-stock in 1870 was $2,103,343. The chief export is lumber, of which no less than 300,000,000 feet were sawn in the 60 existing mills in 1875. There is considerable flour-milling, and productive fisheries of salmon, halibut, cod, and oysters. In 1878 there were 187 miles of railway in W. T., the chief town of which is Olympus (pop. 1203). The territory was organised in 1853, and reduced to its present limits by the exclusion of Idaho in 1863. A dispute with the English as to the possession of the Puget Sound region, begun about 1828, lingered on for years, and the American claim to the islands in the Gulf of Georgia was not allowed till 1873.

Wash'ington and Lee Univer'sity, at Lexington, Virginia, United States, was originally the Augusta Academy at Grenville, and was chartered in 1782. A grant of stock from General Washington was commuted by the legislature to an interest-bearing fund of $50,000, and this sum has been augmented by gifts of $25,000 from the Cincinnati Society in 1803, and of $40,000 from Mr. J. Robertson in 1826. The institution comprises 13 elective schools, including schools of law, engineering, and applied science. Scholarships are open to divinity students, sons of ministers, intending journalists, teachers, and practical printers, and the foremost pupils of certain high schools and academies. Degrees are only gained by examinations in the several schools. The government is vested in the president and faculty, under a board of trustees. In 1878 there were 300 students and 20 instructors, while the library had 12,000 vols. General Robert E. Lee was succeeded as president on his death in 1870 by his son, General G. W. Custis Lee. There are two other institutions of a somewhat similar name, (1) the University of Washington Territory, chartered in 1860, and organised as a graded school in 1872; (2) Washington University, at St. Louis, Missouri, incorporated in 1852, and having a law school (1867), and the library of the O'Fallon Polytechnic School, containing 30,000 vols.

Wash'ington City, the capital of the United States and seat of the Federal government, situated in the district of Columbia, on the left bank of the Potomac, 106 miles above its mouth, 39 S.W. of Baltimore, 137 from Philadelphia, and 227 from New York by rail. It ranks, in respect of population, twelfth among the cities of the United States, and bears a peculiar character from the circumstance that it was called into existence

to be the seat of the national legislature. After the district of Columbia (q. v.) had been ceded by Maryland as a site for the city, the superintendence of its laying out was left to President Washington and Thomas Jefferson, Secretary of State, by act of Congress of 30th March 1791. A French engineer, Major L'Enfant, prepared the plans, based on the topography of Versailles, and introducing broad transverse avenues, spacious squares, &c. The situation was well chosen—a plateau 100 feet above the river, between Anacostia River and Rock Creek, which separates it from Georgetown (q. v.). To this plateau, Capitol Hill, the ground rises in easy ridges, and to the E., N., and W. extends an amphitheatre of woody hills. Originally called the 'Federal City,' it received its present name from the commissioners. The grand scale of the design left it little more than a design for many years, during which it was known as 'the city of magnificent distances.' No street was less than 70 feet wide, while some were 160, and the aggregate length of the streets is at present 264 miles. The avenues, 21 in all, are named after the various States, and the principal one, Pennsylvania Avenue, is a magnificent thoroughfare, 130 feet wide, reaching from the Anacostia, past the Capitol and the President's House, to Georgetown. It consisted originally of three roadways, with a double row of Lombardy poplars, but these trees were cut down in 1832, and the roadway thus broadened was paved in 1876 with concrete, and is acknowledged to be the finest drive in the country. The Massachusetts Avenue has a length of 4½ miles. Among the many parks and open places are the Capitol grounds, 52 acres; President's grounds, 20; La Fayette Square, 7; the Park or Mall (not yet fully opened, 1879), 100; Judiciary Square, 19; the Arsenal grounds, 44½, and the Navy-Yard, 27. The city in all covers 6111 acres, or 9½ sq. miles, having a frontage on the Potomac of 4 miles, on the Anacostia of 3¾. The proportion of land unbuilt on, which exceeds that perhaps of any other city, has greatly influenced the public health, and the death-rate is as low as 2 per cent. The city is divided into four sections, and the streets, on the 'Philadelphia plan,' are, within each section, called either by the letters of the alphabet, or by numbers, from First to Twenty-Eighth, according as they run E. and W., or N. and S. The principal building is the Capitol, a freestone edifice, which was erected in 1818–25, and to which two immense wings in white marble were added, 1851–59. Its entire length is 751 feet, its greatest depth 324 feet, its height to the roof 70 feet, its area 3½ acres. Its front has 68 Corinthian columns, and from the centre springs a great iron dome, crested with a statue of Freedom (1863), at a height from the ground of 285½ feet. The entire cost of the structure was $13,000,000. The interior of the Rotunda is adorned with frescoes by Brumidi, Trumbull, Vanderlyn, Weir, and Powell, and the façade and portico with sculptures by Crawford, Greenough, and Persico. The Senate Chamber, in the N. wing, is 113 by 81 feet, with seats for 76 senators and 1000 spectators. The S. wing is occupied by the House of Representatives, 139 by 93 feet, and seated for 300 members and 1500 others. The Library of Congress, which receives a copy of all publications, comprises over 310,000 vols. (35,000 law). The old Senate Chamber, in the central building, is now the Supreme Court, and the old Hall of Representatives, a fine semicircular chamber, was made a National Memorial Hall by an Act of 1864. Other important buildings are the Treasury Department, an Ionic structure with monolithic columns 31½ feet high, erected (1836–64) at a cost of $6,000,000; the Patent Office (1837–64; partly destroyed by fire, 1877), in pure Doric, with three fronts of Maryland marble; the Post Office (1855), in Corinthian style, with a frontage of 300 feet; the ornate, brick-built Agricultural Department (1868), situated in beautiful grounds 10 acres in extent; the Naval Observatory (1844), with an electric time-signal and great equatorial telescope (1873), the object-glass, one of the largest in the world, being 26 inches, and costing $47,000; and the Army Medical Museum, containing valuable archives and a library of 40,000 vols. The President's House, or White House (1818–29), is a plain Ionic freestone edifice, painted white, and standing in grounds adorned with fountains and shrubbery. The new building for the State, Navy, and War Departments (begun 1871, and not finished 1878), a massive Renaissance structure, with a Mansard roof, has a length of 567 feet, and a breadth of 471. It is entirely of granite, and will cost $7,000,000. The Washington National Monument, begun in 1848, came to a stand-still when 174 feet of the column had been raised at a cost of $230,000. In 1876, however, Congress appropriated $200,000 to its completion as a plain obelisk, 70 feet square at the base, and 470 feet high. W. C. has few good monuments; one of the best is Bell's statue emblematic of Emancipation (Abraham Lincoln unfettering a slave), erected in 1876. There are in all 120 churches, but they are inferior in architecture to the hotels and boarding-houses scattered throughout the city. There are numerous scholastic and benevolent institutions, the former comprising the Smithsonian Institution (q. v.), the Columbian University, Gonzaga College (Roman Catholic), Howard University for coloured youths, and the law school of the National University. W. C. publishes 5 daily and 12 weekly journals, and the places of amusement include a good theatre and opera-house. A water supply of 80,000,000 gallons daily can be procured by means of an aqueduct (cost $3,500,000) from the Great Falls of the Potomac, 16 miles above the city. W. C. is connected with the Virginian shore by 3 bridges across the Potomac, which is here a mile wide. There is little trade and less manufacture, but as a political focus the city is maintained in prosperity by a constant influx of visitors, many of whom are attracted by the genial climate and the gay social life. Pop. (1875) 125,000, of whom 73,731 are white, 35,455 coloured, and 13 Indians. Founded in 1791, W. C. was little else than a gigantic failure for more than half a century. In 1839 George Combe wrote that it looked 'like a large straggling village reared in a drained swamp.' Down to 1871 the grounds and avenues were sadly neglected, but in that year Congress, having abolished the municipal governments of W. C. and Georgetown, and created the district of Columbia a territorial government, an enterprising Board of Works was established, which by 1876 had created a public debt of $25,000,000, the cost of improvements, including the paving of 160 miles of streets, and the planting of 29,000 trees. During the Civil War, W. C. was several times in danger of attack, and was protected by an immense cordon of earthworks. It served as a great military depôt, and most of its public buildings, including the Capitol, were converted into temporary hospitals. On Arlington Heights, on the Virginian shore, are the graves of 15,000 Union soldiers.

Wash'ington, a town of Missouri, U.S., on the S. bank of the Missouri River, 54 miles W. of St. Louis by rail. It lies on a high ridge running parallel with the river, on which a steam-ferry plies. There are seven churches, one of the finest being the Roman Catholic church of St. Borgia. Prominent among the public buildings is the Jeffries High School, a Catholic institution. W. has a large trade in agricultural produce, and its industries comprise steam, flour, and saw milling, beef and pork packing, tanning, &c. Two rich deposits of fire and potter's clay are extensively wrought, and large quantities are shipped to St. Louis. Pop. (1870) 5614.

Wash'ita, or **Ouach'ita**, a river of the United States and an affluent of Red River, flows in a S.E. direction through Arkansas and Louisiana, draining a rich cotton and corn country for a distance of 600 miles. It receives the Saline River, La Fourche, Tensas, and Little Missouri, and is navigable throughout the year by steamboats to Camden, a distance of 300 miles. The *False W.* traverses the Indian territory, and joins the Red River above Preston, in Texas.

Wasp, the name applied to various species of *Hymenopterous* insects of the family *Vesparia* (Latreille). The body is slender, and the antennæ are elbowed or bent. The mandibles are large, and the maxillary palpi 6-jointed. The wings are long and narrow, and the hind shanks and tibiæ of the legs smooth. The larvæ are fleshy grubs. In the wasps we find *social instincts* frequently exemplified, as in the bees. The higher wasps build papery nests, but lower genera may burrow in the ground. The genus *Vespa* includes typical species, such as *V. maculata* and *V. arenaria* (the latter the yellow W.), both of which construct papery nests in the form of galleries, the opening of the nest pointing downwards. *V. Orientalis* builds cells of clay. The Hornet (q. v.) is merely a species of W. Wasps live upon other insects, and spoil and pillage other species of Hymenoptera. They attack honey bees, and are known to destroy flies and butterflies. They are destructive to fruits, and will even devour raw meat. The jaws and not the sting form their chief organs of attack.

The Wood wasps and Sand wasps form the family *Crabronidæ*, in which the head is large and of carboidal form, the fore feet

adapted for digging, and the larvæ short and thick. These wasps make their nests in rotten wood, or in the soft parts of plants.

Waste, in English law. See COMMON; IMPEACHMENT OF WASTE; DILAPIDATION; TENANT FOR LIFE; TIMBER, LAW REGARDING. A strip of W. land adjoining a highway belongs to the owner of the adjoining soil.

Waste Land, a term applied to land not brought under tillage, though capable to some extent of cultivation, in countries whose agricultural produce is inadequate for the wants of the population. In the United Kingdom, for example, of the 77,828,947 acres constituting its area, only 47,326,615 were in 1878 enclosed and cultivated, the remainder being distributed in woods and plantations, uninclosed pasture, moorlands, heaths, downs, peaty and marshy lands, and hilly wastes. Considerable portions of this W. L. are from altitude or unfavourable climatic conditions hopelessly unimprovable; other parts could be rendered productive at an excessive outlay, but would scarcely prove remunerative; still many large tracts—estimated in the aggregate at about 16,000,000 acres—might with enterprise and skill be profitably added to the food-producing area of the kingdom. Several hundred thousand acres have been reclaimed during the present century. The means adopted for the reclamation of W. L. vary with the nature and situation of the soil. The principles of draining, trenching, liming, and fencing are general. Stony ground is trenched with the spade, as the plough cannot be advantageously employed. Mossy lands are treated with large quantities of clay, sandy earth, or marl, to afford firmness, while most reclaimed land is the better of an application of lime. Irrigation is useful for some lands, and with the subject of reclaiming W. L. that of the profitable utilisation of sewage is intimately associated.

Wast'ing Pal'sy is one of the terms applied to *Tabes Dorsalis* (q. v.).

Wast'water, in Cumberland, the seventh largest of the English Lakes, lies 14 miles S.S.W. of Keswick, from which it may be gained by the steep Sty Head (1560 feet) or the Black Sail Pass (1690 feet). Shut in by rugged mountains, among them Scafell Pike (3208 feet), the highest point in England, W. presents an aspect of wild and gloomy grandeur. It is 3 miles long by half a mile wide, and has a depth of 270 feet.

Watch. The invention, sometime during the reign of Louis XI., of a *main-spring* as a substitute for the weights suspended by cords hitherto employed to drive the train of a clock, was the first step towards the construction of a pocket-timepiece, known as a W., for it then became possible to reduce a time-measurer to portable dimensions. Watches were probably first constructed at Nürnberg early in the 16th c.; at least among the earliest known are the 'Nürnberg animated eggs,' so called from their ovoid shape. They have wheels of steel, De Wick's 'verge' escapement, and an hour hand only. The *fusee* was invented about 1530 to equalise the varying force of the mainspring. At first it was connected by a catgut cord with the barrel enclosing the mainspring, but about 1665 a chain was substituted. Fanciful forms were common among early German and French watches, and sometimes rock crystal was chosen as a material for the cases in order to display the mechanism. Flat circular forms were introduced about the time of Louis XIII. In 1658 Hooke in England and Huyghens in Holland simultaneously applied a coiled spring to the balance-wheel to control its vibrations, accomplishing for it the part that gravity plays in the pendulum. Repeating watches were invented by Barlow in 1676. Quare shortly thereafter added a minute hand, and about 1700 Facio of Geneva introduced the practice of setting the pivots in jewels. Of the subsequent mechanical improvements which mark stages in the progress towards the production of a perfect time-keeping W. may be mentioned the horizontal escapement of Graham, the going fusee of Harrison, the lever escapement of Savage and others, and the chronometer escapement of Arnold and Earnshaw, besides the numerous compensation devices applied to the balance-wheel or balance-spring for the purpose of correcting irregularity in the vibrations of the latter arising from its expansion and contraction through changes of temperature. In 1764 Harrison gained a premium of £20,000 offered by the English Parliament for a chronometer sufficiently accurate for purposes of navigation. See HOROLOGY.

W.-making is an important industry in England, Switzerland, France, Germany, and the United States. London is unrivalled for the production of watches of the highest quality. Lancashire, Prescot, and neighbourhood produce about 120,000 movements yearly, partly by the aid of machinery, which was introduced in 1866. Coventry, Birmingham, and Liverpool are also manufacturing centres. The fusee and lever escapement are features of the ordinary English W., which is famed for durability and accuracy. The watches manufactured in France at Besançon and the immediate neighbourhood, and in Switzerland at Neuchâtel, Locle, &c., are characterised by lightness, good timekeeping qualities, and cheapness. They have a 'going barrel,' which renders a fusee unnecessary, and a horizontal escapement. The minutest subdivision of labour is practised. In Switzerland 40,000 persons are engaged in the industry, each of whom makes on an average forty watches annually. Till late years the Swiss held the markets of the world for cheap watches, but the competition of Besançon and especially of the United States have seriously diminished their exports. In the construction of complicated watches, such as repeaters, the Swiss have no rivals. Since 1850 W.-making has developed in a remarkable manner in the United States. The leading principles of the industry are great simplicity of mechanism consistent with perfect reliability in time-keeping, and the use of labour-saving machines. The fusee and chain are discarded, a wide and free motion of the esochronous balance-spring having been found sufficient to govern and equalise the movement of the train. The movements and other parts of a W. are made by specially contrived machines, to a great extent automatic, by which great precision and uniformity are attainable. The corresponding parts of watches of the same grade are accordingly interchangeable. The idea of using machinery originated with Dennison and Howard, working watchmakers of Boston, and they first carried it into practice at Roxbury in 1850. Half-a-dozen factories are now in operation in the United States; the two principal are those of the Waltham (Massachusetts) Company, employing 900 persons, half of either sex, and the Elgin (Illinois) Company (700 persons). Here 375 movements are made daily; and whereas in England and Switzerland one man can produce only 40 watches a year, at Waltham 150 are turned out per man. The total annual product of the Waltham factory is upwards of 100,000 W.-movements, 50,000 silver cases, and 18,000 gold cases, and the value of the whole exceeds $2,000,000. It is only in the American factories that the complete parts of a W. are made and put together under one roof.

W. cases of British manufacture must be assayed and stamped at the Goldsmiths' Hall, London, or at some provincial hall. The large number of 32,888 gold and 112,323 silver cases were marked in London during the year ended 29th May 1875.

W. dials that are luminous in the dark have recently come into vogue. The luminosity is due to a coating of a phosphorescent body, such as sulphide of barium or sulphide of calcium, which is attached to a paper or cardboard dial by means of adhesive varnish. See Denison's *Rudimentary Treatise on Clocks and Watches* (new ed. 1867), and Schilling-Baumann's *Ueber Uhren; deren Geschichte und Behandlung* (Zür. 1875).

Watch, the term used to indicate the portions of time into which the night is divided for sentinel duties. Hence, as on shipboard, the word is applied to the sections into which the crew is divided for such purposes.

Wat'er, the most widely distributed of all minerals, exists at ordinary atmospheric pressure and temperature as a clear, limpid liquid, entirely free from taste or smell, and with neither an acid nor an alkaline reaction. Though colourless in small quantity when pure, it has a distinctly blue colour when viewed in mass. In its liquid form W. covers about three-fourths of the surface of the globe, besides permeating the porous strata which form the earth's crust. Its density, which in the liquid state is about 770 times that of the atmosphere, varies with the temperature, attaining a maximum at 4° C. When the barometer column stands at a height of 760 millimeters (29·922 inches), the weight of a cubic centimetre of water at this maximum temperature equals the weight of 1 gramme, so that a *litre* of water at 9° and 760 mm. pressure weighs a *kilogramme*. Under the same barometric pressure, W. freezes at 0° C. and boils at 100 C.; indeed, it is by these changes of state that the two standard temperatures of all our thermometric scales are deter-

mined. (See THERMOMETER.) In the act of melting ice contracts, and hence, in accordance with the dynamical theory of heat, the freezing point of water or the melting point of ice is lowered by increase of pressure. (See ENERGY, GLACIERS, THERMODYNAMICS.) On the other hand, W. expands when becoming steam, so that its boiling point is raised by increase of pressure. In its liquid form W. is slightly compressible, so slightly that it long resisted attempts to measure its compressibility. For an additional atmosphere of pressure its volume is reduced ·000047, or by about one twenty-thousandth part. According to Perkins, its volume is reduced by $\frac{1}{12}$th under 200 atmospheric pressures. Its specific heat is greater than that of any other known substance, and is the unit in terms of which the specific heats of other substances are expressed. For this reason W. is valuable as an equaliser of temperature, since the change of temperature produced by absorption or abstraction of heat is smaller than the corresponding change for any other substance. Not only so, however, but in converting it into ice or steam, during either of which processes no change of temperature occurs, a large quantity of heat is evolved or disappears, being transformed from or into a less evident form of energy. Thus, in converting W. into steam, 5·37 times as much heat is used as is required to raise the same mass of water from 0° C. to 100° C. W. vapour is always present in the atmosphere; and for every temperature there is a definite maximum quantity which the atmosphere is able to retain. (See VAPOUR.) If the atmosphere is dry, *i.e.*, does not contain its maximum quantity of vapour, the W. filling the oceans, lakes, rivers, streams, &c., is undergoing evaporation, and must therefore be cooling in order to supply the heat which must disappear so that this evaporation may take place. On the other hand, if the atmosphere is saturated there is no evaporation; but if the temperature of the air falls, precipitation takes place in the form of rain, mist, dew, snow, or hail. This condensation of vapour is accompanied by an evolution of heat; and hence, generally, whatever change of temperature the atmosphere suffers, the corresponding changes produced in the condition of the atmosphere as regards the W. vapour which it contains tend to resist by their thermal effects the original variations in temperature. The various conditions under which the moisture in the air is precipitated are noticed under CLOUDS, DEW, RAIN, HAIL, and SNOW. See also RIVER and SEA for details regarding W. in its geological relations as a destructive and conservative agent.

Chemically, W. is a compound of hydrogen and oxygen, being represented by the formula H_2O or HOH. By the ancients it was supposed to be one of four elements of the physical universe, and its compound character was not proved till Cavendish in 1781 produced it synthetically by the explosion of a mixture of hydrogen and oxygen. Watt also claimed to have discovered the true nature of W.; and after the death of both, a bitter controversy continued for a long time regarding their respective claims. There seems no doubt that Cavendish had the priority, though very probably Watt made his researches independently. W. is thus really an oxide of hydrogen, resembling in constitution either oxide of potassium (K_2O), or caustic potash (KOH). As already noticed, however, it possesses neither acid nor basic characters. With strong acids such as anhydrous sulphuric acid or anhydrous nitric acid it forms definite compounds (H_2SO_4 and HNO_3), which retain strong acid characters; while it combines similarly with strong bases forming definite compounds, such as caustic potash (KOH) or caustic soda (NaOH), which also retain their alkaline properties. These hydrated acids or bases, however, have the same constitution as the salts which result, if instead of indifferently basic or acid W. a strong acid or base is substituted. This view of the action of W. is interesting as showing how difficult it is to draw a hard and fast line between the three groups of compounds, salts, bases, and acids, which are recognised in chemistry. The real chemical nature of W. is still far from being understood, notwithstanding that it is the most common of all known compounds. Even in the simpler cases of mere solution, it is as yet impossible to say definitely what is going on. The fact that many strong undiluted acids do not act upon bases so readily as they do when slightly dilute, indicates the great importance of W. in aiding chemical action; and the so-called W. of crystallisation, which must be present in many salts before they can take the crystalline form, bears intimately upon the same question. Though the compound character of W. was first demonstrated by synthesis, it is much more convenient now to demonstrate it by analysis, *i.e.*, to break it up directly into its component parts. This dissociation may be effected by raising steam to a high temperature, or by passing steam over red-hot iron, which absorbs the oxygen and lets the hydrogen pass over. Electrolysis (q. v.), however, affords the readiest means at our disposal to effect this decomposition. After adding a little acid to improve the conducting power of the W., a current is passed through the liquid, and hydrogen and oxygen are given off, the former at the electrode by which the current leaves the liquid, the latter at that by which the current enters.

Wat'er-Bed, Hydrostat'ic Bed, or **Float'ing Matt'ress,** devised by Dr. Neil Arnott, one of the Queen's physicians, consists of a trough of the dimensions of a wide sofa or a bed, having 6 or 7 inches depth of water in it, and over it a caoutchouc covering on which clothes and pillows are laid as in a common bed. A more convenient and portable contrivance is the Water Mattress, consisting of a caoutchouc or waterproof bag of the size of an ordinary mattress, which may be filled with water of any degree of temperature, or with air, as may be desired. The W.-B. is exceedingly useful in many diseases, but it is frequently a considerable time before the patient can become accustomed to its use, and some can never be reconciled to it. A person weakened from disease often suffers considerable pain from pressure, and it is necessary for the comfort of the patient that his position be changed frequently. This is in great measure obviated by the W.-B. In other cases sensation is blunted, and the patient remaining for lengthened periods in one position, surfaces exposed to long-continued pressure are apt to slough, causing bed-sores, and such may only be discovered accidentally. In such cases the W.-B. relieves the pressure, and thus prevents the formation of bed-sores. In all diseases in which the patient is confined long to bed, as in lingering consumption, paralysis, disease of the spine, and fevers with delirium, the W.-B. is of great value.

Wat'er-Brash. See PYROSIS.

Wat'er Bug (otherwise 'Water Scorpion and 'Water Boatman'), the name given to a section of the *Hemipterous* family *Notonectidæ*. The hind legs are long, and adapted for swimming. The body is prismatic in form, convex above and flat beneath, and the head is as large and as wide as the body. The antennæ are four-jointed. *Notonecta* is the typical genus of the family. To the allied family *Nepidæ* also belong species of the W. B. more especially named 'Water Scorpion.' *Nepa cinerea* is a familiar species. In *Nepa* the body terminates in a long breathing-tube, and the antennæ are three-jointed. The W. B. is predaceous, living chiefly on the larvæ of other insects.

Wat'erbury, a city of Connecticut, U.S., 88 miles N.E. of New York by rail. It has eleven churches, a city hall, a large public hall, and a library of 18,000 volumes. W. supports one daily and two weekly newspapers. There are manufactures of brass, iron, copper, and other metallic goods. The city possesses waterworks of great size. Here the co-operative system has always largely prevailed, and there are about thirty joint-stock companies with a capital exceeding £1,200,000. Pop. (1870) 10,826.

Wat'er-Cal'trops and **Wat'er-Chest'nut.** See TRAPA.

Wat'er-Col'ours are pigments carefully ground up with water and isinglass or other mucilage instead of oil. They are prepared in the form of small cakes dried hard, or kept moist by the addition of honey. See PAINTING.

Wat'er-Cress. See CRESS.

Wat'er-Dog, a variety of the Dog having a curly coat, long ears, a rounded head, and webbed toes. It seems to be allied to the Poodle (q. v.), but differs from the latter in its firmer set and stouter body, and in its larger size. The W. D. is highly intelligent, but less so than the Retriever (q. v.). It is usually of a greyish white varied with black and brown.

Wat'er-Drop'wort (*Œnanthe*), a genus of glabrous herbs, often aquatics, belonging to the natural order *Umbelliferæ*. There are about 20 species, distributed through N. temperate regions, S. Africa, and tropical Australia. In this genus the leaves are much divided, and the umbels compound, generally

without a common involucre, but with partial involucres of many narrow bracts. The fruit is cylindrical or ovate, and the carpels marked with five convex ribs, between which, within the rind, run as many vittæ. *Œ. crocata* is a rank poison, of varying intensity. It is a common plant of marshes, ditches, &c., through Britain, and numerous fatal accidents have occurred from its thick, whitish tubers being mistaken for the root of the parsnip, or the plant itself for celery. *Œ. phellandrium*, the fine-leaved W.-D., is less poisonous.

Wateree′, a river of N. and S. Carolina, United States, rises in the eastern part of N. Carolina, and flows direct S. to Fort Mott, where it unites with the Congaree to form the Santee. It is navigable to Camden, 200 miles from the sea. Above Fishing Creek in N. Carolina it is called the Catawba.

Wat′erfalls are formed by a sudden change in level of a river's bed, so that the water pours vertically downwards in a more or less unbroken sheet. They are most frequent in mountainous districts, where, however, they are generally small as regards their volume of water, and present very different aspects according to the season of the year. The most magnificent known W., those of Niagara, the Congo (Livingstone), the Zambesi, &c., are situated in comparatively level country, and their grandeur is due to the immense and steady volume of water which is precipitated several hundreds of feet. At the base of the fall a fine spray is always kept in suspension, which in certain lights displays gorgeous rainbow tints. Geologically, the action of a waterfall is very similar to the action of rivers in general, wearing away the channel through which it flows and the ledge over which it is precipitated. All W. therefore tend to retreat up the river's course, the rate of erosion of Niagara being for example, according to Lyell, about 1 foot annually. Of the more remarkable falls we may specify, besides those mentioned, the Tequendama Falls in Colombia, S. America (476 feet high and 38 feet broad), the Yosemite Falls in California (an unbroken fall of 5500 feet, and a total fall of 6600), the Gerseppa Falls of the West Ghauts, near Honawar (in four cascades, the first of which is 884 feet high), the Kaveri Falls near Madras (368 feet), the Missouri Falls in N. America (a series of cascades with a total fall of 357 feet), the Staubbach Falls in Switzerland (998 feet), the Rheinfall near Schaffhausen (60 feet high and 380 feet broad), the Gavarnie Falls of the Pyrenees (1325 feet), and the Orco Falls at Monte Rosa (2400 feet).

Wat′er-Flea, the name given to various small genera of *Crustaceans*, belonging to the order *Entomostraca* (q. v.), and to various sub-orders of that group. It is common in freshwater ponds and brooks, and lives in pure, potable waters (see CYPRIS and CYCLOPS). The *Daphnia pulex* is the 'Branch-horned W. F.,' and may be readily recognised by its large and biped antennæ. The body is enclosed in a bivalve shell, but the head is distinct. The gills are attached to the five pairs of thoracic legs. The large antennæ serve as swimming-organs.

Wat′erford, an Irish maritime county in the province of Munster, bounded W. by Cork, N. by Tipperary and Kilkenny, E. by Wexford, and S. by the Atlantic. Area, 461,552 acres; pop. (1871) 123,510, of whom 96,235 were Catholics, while 3821 spoke only Erse, 43,516 both Erse and English. Mountains, containing slate and quartz, attain an elevation of 2609 feet, and are parted by valleys belonging to the limestone series, while the principal rivers are the Suir and Blackwater. Rich pastures alternate with marshes and good light land, and the climate is moist, the rainfall of 1877 being 51·82. Of 90,581 acres under crops in 1878, 13,441 were in wheat, 25,006 in oats, 1652 in barley, bere, and rye, 14,393 in potatoes, and 23,929 in meadow and clover, while woods and plantations covered 20,158 acres in 1877. The live stock included 13,948 horses and mules, 4324 asses, 93,732 cattle, 66,724 sheep, and 53,325 pigs in 1878, when the rateable valuation of W. was £316,665. Copper-mining, quarrying, and the cotton manufacture afford some employment, but fishing (1101 men and boys in 1878) and agriculture are still the staple industries, though both have declined with the fall in the population, the number of emigrants being 66,483 during 1851–77. W. and Dungarvan are the only towns in the county which return two members to Parliament.

Wat′erford, the capital of the preceding county, itself a county of a city, stands on the right bank of the Suir, and is connected with its N. suburb of Ferrybank, by a bridge 832 feet long. Of six Catholic places of worship, including a cathedral, the finest is the Dominican church of St. Saviour, erected (1878) in the Italian style at a cost of £11,000; and the Protestant Episcopalians have also a cathedral and two churches. Other buildings are the Protestant Episcopal palace, the Catholic College of St. John, St. Dominic's Industrial School (with 120 inmates in 1876), four convents, a town-hall, market-house, &c. Up to 1871, £23,000 had been expended in deepening the channel of the Suir, whose southern bank is fringed for a mile by a spacious quay, while on the Kilkenny side is a shipbuilding yard, with a patent slip, graving-bank, and dock. In 1878 there entered the port 2536 vessels of 675,397 tons, and cleared 2527 of 673,539 tons; and in 1877 the imports amounted to £676,599, the customs to £62,976, and the imports (chiefly agricultural produce) to £13,527. Besides two immense bacon-curing establishments, W. has iron-foundries, flour-mills, breweries, &c. It publishes nine newspapers, and returns two members to Parliament. Pop. (1871) 23,349, of whom 20,604 were Catholics and 1861 Protestant Episcopalians. A memorial of W.'s foundation by the Dane's in the 9th c. is 'Reginald's Tower' (1003), which has witnessed the city's capture by Strongbow (1170), the repulse of Cromwell and surrender to Ireton (1649–50), and the embarkation of James II. after the Battle of the Boyne (1690).

Wat′er-Glass consists of a compound of silica (quartz or pure sand) and either or both of the alkalies soda and potash. The silica and alkaline substances are melted together as in the manufacture of glass, and the resulting compound is a transparent glassy mass differing only from ordinary glass in the circumstance that it is soluble in water, whence the name W.-G. or soluble glass. Its solution has many important applications in the arts, being used in calico-printing as a 'dung substitute,' as a substance for rendering paper, textiles, and wood uninflammable, for preserving wood, for mixing with pigments, and for the preparation of a mineral cement and artificial stone. It also plays an important part in the art of stereochromy in the preparation of mural decorations and paintings, which are practically unaffected by exposure to all atmospheric influences.

Wat′er Hemlock. See HEMLOCK.

Wat′erland, Daniel, D.D., 'the most learned of contemporary divines', was born in Lincolnshire, 14th February 1683, studied at Cambridge, became master of Magdalen College, Chaplain to George I., and Canon of Windsor. He died 23d December 1740. W. was an able and zealous defender of the orthodox faith against the English Deists and other 'infidels' of the period. He builds principally upon the historical argument. His writings are entirely controversial: the chief are *A Vindication of Christ's Divinity, being a Defence of some Queries relating to Dr. Clarke's Scheme of the Holy Trinity* (1719), followed by a second (1723) and third (1725) Vindication; a *Critical History of the Athanasian Creed* (1724), also directed against Clarke; *Christianity vindicated against Infidelity* (in three parts, 1730–32), a reply to Tindal's 'Christianity as old as the Creation;' and a *Review of the Doctrine of the Eucharist* (1737), directed against Hoadley's rationalistic interpretation of that ordinance. A complete edition of W.'s works, with a Life by Bishop van Mildert, was published at Oxford (11 vols. 1823–28; new ed. 6 vols. 1843). See Abbey's *English Church in the 18th c.* (Lond. 1879).

Wat′er-Lil′y, a current name for several well-known species of aquatic plants belonging to natural order *Nymphæaceæ* (q. v.). The white W. L. (*Nymphæa alba*), which has a wide distribution in the N. hemisphere, is frequent in lakes, ponds, and water-courses throughout Britain, its large and chaste flowers claiming precedence for beauty among the indigenous flora. *Nymphæa lotus* has similar flowers but tinted with pink, and has strongly-toothed floating leaves; it is the white lotus of the Nile. The blue lotus (*Nymphæa cærulea*) has fragrant blue flowers. Several species and numerous varieties of W. L. are in cultivation as ornamental plants, including the above and *Nymphæa odorata* of N. America. In India the seeds are used as food. In the allied genus *Nuphar* the flowers are yellow, and the common species (*Nuphar luteum*) is known as the yellow W. L. It is a frequent British plant of still waters. The flowers are fragrant with an alcoholic odour, hence its further name of 'brandy bottle.' The rootstock abounds in tannic acid. See LOTUS and VICTORIA.

Waterloo', the Belgian village of Brabant, 12 miles S.E. of Brussels, where on 18th June 1815, two days after the actions of Ligny (q. v.) and Quatre Bras (q. v.), Napoleon with 72,247 Frenchmen was defeated by Wellington's army of 69,894 men (25,389 British, 10,995 Hanoverians, 17,488 Netherlanders, &c.). The battle (by Frenchmen named after the village Mont St. Jean, the key of the British position; by Prussians after the farm of La Belle Alliance, the French centre) lasted from 11.30 A.M. till 7 P.M., Bülow bringing up by 4.30 P.M. the first of Blücher's 45,000 Prussians, in time to convert into a glorious victory what otherwise had been a drawn engagement. The loss of the Allies was 23,185 (1120 officers, 11,678 British and Hanoverians, 6999 Prussians, &c.), that of the French 18,500 (32,000 by some accounts), with 7800 prisoners and 227 cannon taken. See, besides works cited under NAPOLEON I. and WELLINGTON, General Mercer's *Journal of the W. Campaign* (2 vols. Edin. 1870); Colonel Chesney's *W. Lectures* (3d ed. 1874); Königer's *Krieg von* 1815 (Leip. 1865), and De la Tour d'Auvergne's *Étude de la Campagne de* 1815 (Par. 1870).

Wat'er-Mel'on. See MELON.

Wat'er-Ou'sel. See DIPPER.

Wat'er-Power. Under this heading we conveniently consider the various means by which the energy of moving water may be utilised. To make such a source of energy effectual, it is necessary and sufficient to have the water falling from a higher to a lower level; in other words, the water must have what is technically called a 'head.' Such conditions more or less favourable exist in all streams, though in many cases the fall is so slight and therefore the velocity of the water so small that practically no useful work can be obtained. In such case, by the construction of dams or otherwise, the energy may be stored up as potential energy in a large mass of water to be transformed at will. Even where the stream is one which is directly available for performing useful work, it is usually advisable to collect the water in reservoirs, since the quantity of flow of most streams varies considerably with the seasons. Even with such precautions the supply of water may be far from uniform, overflowing the dams in the wet season and hardly filling them in the dry. Given the available fall and the total quantity of water which flows in a given time, the potential energy which is lost is expressed in foot-pounds by the product of the mass in pounds multiplied by the height through which the water has fallen. This energy is mainly transformed into the kinetic energy of running water, while part is transformed into heat and sound. If the former portion could be wholly transformed into useful work, the water would be brought to rest; but as this is never practically realised, we see that the *available* energy of a fall of water is much smaller than the total transformable energy. Of the various machines by which the necessary transformation is usefully effected, the most common are what are known as waterwheels, in their several forms of turbines, undershot wheels, breast wheels, and overshot wheels. The last three are very similar in construction, and are made to rotate round a horizontal axis by the action of the water upon the floats which are fixed at equal intervals more or less radially round the circumference of the wheel. In the *overshot wheel*, which is applicable to falls of from 12 to 60 feet, the water is received in the bucket-shaped partitions in the circumference, and by its weight, aided in some measure by the initial impact, drives the wheel round, the upper part moving in the direction of the flow of water. The water escapes below as each partition during the rotation of the wheel is turned face downwards. The *breast wheel* acts very similarly, and is applicable to falls smaller than those for which the overshot wheel can be conveniently used. The upper circumference of the wheel is higher than the feeding channel of the water, which enters at a point usually a little above the centre of the wheel. The *undershot wheel* is used where the momentum only of the current can be utilised, the impact of the water upon the floats forcing the wheel round. There is necessarily a considerable waste of power in the undershot wheel, which was to a certain extent remedied by Poncelet when he introduced curved instead of plane floats. The *turbine* or *vortex-wheel* is usually horizontal, rotating round a vertical axis. In the original form of turbine, invented by Fourneyron in 1823, water was introduced from above into a central chamber, from which it radiated through curved radial chambers. From these it was projected upon the curved floats of the wheel, which was forced round by the reaction of the escaping water. The principle of the action is the same as that of Barker's Mill (q. v.). In all forms of turbines the essential parts are—(1) fixed vanes, called guides, for giving direction to the water; (2) vanes at the circumference for receiving the water; (3) a gate for regulating the quantity of water, and therefore the velocity of the wheel; and (4) a shaft for transmitting the rotatory motion. Besides the outward-flow turbines, like that described above, in which the guides are *inside* the wheel, there are also inward-flow turbines, which have the guides *outside*, and the parallel-flow turbines, in which the guides are *above* the wheel. In the turbine both the direct impulse and the reaction of the water are utilised; and in this way the turbine has decided advantages over other forms of waterwheels. Though it is from rivers and streams that we derive all the W. P. which is profitably used, there is no doubt that in the tides we have a great and remarkably constant source of energy, if it could be utilised. Suggestions have not been wanting as to methods for utilising this energy, but as yet nothing practical has resulted.

Wat'erproofing. The process of rendering any substance impervious to water. W. is mainly applied to woven fabrics, and is most effectually accomplished by the use of vulcanised indiarubber (see CAOUTCHOUC). Garments of cloth covered with indiarubber possess the drawback of being also impervious to air; the disadvantage has to some extent been removed by perforating the garment in parts concealed from sight. Ballard's process for W. fabrics without making them airproof consists in immersing the cloth in a solution of acetate of alumina and drying in a current of air. Clamond of Paris has recently patented the application to cloth of a solution of paraffin, the solvent being afterwards driven off by heat. Mr. Berthon's recipe for W. and airproofing canvas for his collapsing boats is as follows: To 6 oz. of hard soap add 1½ pints of water, and when boiling add 5 lbs. of ground spruce ochre, ½ lb. patent driers, and 5 lbs. boiled linseed-oil. Greater flexibility is obtained by omitting the ochre. The Chinese use a composition of boiled oil, soft soap, and beeswax for W. calico, which when so treated withstands the effects of climate and rough usage much better than European waterproofed fabrics.

Wat'er Scorpion. See WATER-BUG.

Wat'ershed. See RIVER.

Wat'erspout, a phenomenon frequently observed at sea, is caused by the descent of a vortex of cold air condensing the moisture in the stratum through which it penetrates, so that the clouds appear joined to the sea by a column of water. It is therefore a whirlwind upon a small scale. See WINDS.

Wat'er-Supply'. It is an obvious fact that the command of an abundant and pure supply of water is a prime necessity to the health, prosperity, and increase of any community. While a population is small in proportion to the area it occupies, the difficulty of procuring a sufficient supply is usually small, but as the inhabitants increase in number, in a rapidly-increasing ratio grow the difficulties and expense of obtaining an adequate and uncontaminated supply. The water-draining from highly-cultivated lands, and the streams which drain populous regions generally, are not in condition to constitute sources of supply for ordinary domestic purposes, and thus, with extending population, public authorities are obliged to go to increasingly great distances, and to incur augmented expense in obtaining a proper W.-S. The difficulties of W.-S. as a national question have begun to make themselves so felt in the United Kingdom that H.R.H. the Prince of Wales invited the Government (March 1879) to appoint a Royal Commission to investigate the question in its national bearings, and doubtless active steps will soon be taken in connection with the subject.

All fresh W.-S. is primarily obtained from rain. The rain which falls on any surface partly disappears by evaporation, is partly absorbed and transpired by the organic life of the region, and partly penetrates into the interior of the earth and reappears as springs, while the remainder as surface water collects into streams and rivers and passes out to the ocean or sea by the main waterway of the area. Only the springs and surface water of any region are available as sources of W.-S., and the various conditions under which the water from these sources is collected

may be embraced under—1, Wells, deep and shallow; 2, springs; 3, lakes or natural reservoirs; and, 4, streams and rivers. Shallow wells, which may be formed in any pervious superficial deposit overlying clay beds or other impermeable strata, are the commonest sources of private supply. Being always sunk in immediate proximity to human dwellings, and being made in highly pervious sand, gravel, or light soil, they are in great danger of becoming receptacles of much imperfectly filtered sewage water. Deep wells again may collect their stores not only from the immediately surrounding surface, but also from a considerable distance. When the waters of such deep wells rise higher than the surface on being tapped, and when consequently no pumping is required, the wells are known as Artesian Wells (q. v.). The depth to which such waters penetrate and the extent of ground they permeate secure their perfect filtration and a most desirable steadiness of temperature and condition. The geological deposits which appear to be most favourable for the percolation and retention of water are the Triassic, Oolite, and Chalk formations, and to a smaller extent the Lower Tertiary beds. The outcrop of the Chalk around London absorbs an enormous quantity of water, which is perfectly filtered by passing through a great mass of porous rocks, and is reached and utilised in London by means of deep wells. Paris, situated on a similar geological basin, is also supplied with a large quantity of water for public purposes from deep Artesian wells. In Liverpool and Birkenhead about 14 millions of gallons are obtained daily from public pumps sunk in the Triassic rocks of that district. Among the numerous plans proposed for increasing the W.-S. of London, one suggestion is to sink deep Artesian wells into or through the Chalk around the city, and to pump the yield from these to artificial reservoirs situated on Hampstead or other high-lying localities. Springs are simply deep wells, the waters of which rise to the surface through natural fissures instead of by channels artificially formed. A large proportion of the W.-S. of Edinburgh is derived from springs situated on the flanks of the Pentland Hills, the waters of which are collected into a series of detached reservoirs formed among the hills. Streams and rivers form the obvious and natural sources of supply of the population of their drainage, area, or catchment basin, and the principle that these alone by right belong to the population within their area has been laid down by the Water Commission of 1869. It is only in their upper reaches, however, that streams are, as a rule, available for domestic supply, as the waters passing through cultivated lands, and populous, especially manufacturing, districts, are so contaminated that they cannot be used for ordinary supply. Rivers further are subject to periodical floods, during which the water is heavily laden with both organic and inorganic impurities, and consequently unfit for use. Again, in periods of drought the supply may fall short, and to guard against both these evils, and maintain a constant supply of equal quality, artificial store-reservoirs on a large scale are absolutely necessary. *Lakes*, on the other hand, are such store-reservoirs prepared by nature, and when they are within the reach of any considerable population they form the best and most economical sources of supply. In the United Kingdom they are only found on a great scale in hilly regions where natural lake-basins have been scooped out by glacial action, and where also the annual rainfall is high. As they generally drain tracts of hilly country composed of primitive rocks where the population is sparse, they are reservoirs of exceedingly soft pure water, and such sources are now eagerly desired by all great cities. In respect of lake-supply no town is more favourably situated than Glasgow, which draws its water from Loch Katrine, a distance of 26 miles. Dundee likewise possesses a pure-lake supply; Manchester persistently seeks to draw its water from the distant Thirlmere in Cumberland; and gigantic schemes have been propounded to carry water to London from the same lake region, or from Bala Lake in N. Wales.

In providing a W.-S. for any community, the first question which should engage the attention of authorities is the purity and quality of the water; next, the sufficiency of the supply; and thirdly, the expenditure involved in making the supply available. The late Dr. Parks (*Practical Hygiene*) divides waters into four classes, 1st, pure and wholesome; 2d, usable; 3d, suspicious; and 4th, impure. The characters of pure water he thus defines: 'It should be transparent, without suspended matters, smell, or taste, and be well aerated. The total solids should not exceed 8 grains per gallon, of which only one should be dissipated by heat, unless it be a chalk water, in which case the total solids should not exceed 14 grains per gallon of calcium carbonate, and should contain only traces of calcium sulphate. The matter destructible by heat (allowance being made for the decomposition of calcium carbonate) should be under 1 grain, and should scarcely blacken; the indications of nitrites should be absent; of nitrates and ammonia extremely slight.' The characters of the 4th class he thus states: 'Any water so turbid as not to be purified by coarse filtration, or with a decided smell or taste, or containing very large quantities of mineral substance (over 50 grains per gallon), and over 4 grains per gallon of destructible (presumed) organic matter, if at the same time the indications of nitrites, nitrates, and ammonia are large, is impure. If on evaporation to dryness and careful incineration there is not only great blackening, but a decided indication of nitric acid fumes, or a smell of burnt horn, or if a large amount of potassium permanganate is rapidly decolorised, the water is impure.' Waters of a quality intermediate between these two should only be used for drinking after filtration, and the kind indicated under class 4th should not be employed under any circumstances as a source of ordinary supply. When there is no alternative but to use such impure water, much may be done to remove its noxious qualities by filtration and other purifying agencies.

Among various tests of the purity of water, the following of easy application may be enumerated. 1st, *Evaporation.* Boil down a measured quantity of water to dryness, and completely dry the ashy residue by heat. If the ash remaining is white and powdery, it is a good sign; but if it contains yellowish and greenish stains, and if, on heating to redness, it partly burns away with an offensive smell of burning animal matter, it may be concluded that the water is tainted with offensive and dangerous sewage matter. 2d. The permanganate of potash test yields valuable indications of organic contamination. The application of this test is thus given by Professor Church: 'Fill a clean white tea-cup with the water to be tested. Add about 60 drops or a drachm of weak sulphuric acid; stir with a clean slip of window glass, now pour in enough of a weak solution of permanganate of potash (Condy's Fluid) to render the water a rich rose colour. Cover the cup with a clean glass plate. Now, if there be much organic matter in the water, the colour will go in a few minutes, and more permanganate may be added and still lose its colour. It must be recollected in using this test that peaty matters and iron salts, which are not necessarily unwholesome, give the same result.' The presence of common salt, which, except in situations near the sea, or in salt-yielding regions, when it exceeds about a grain per gallon, is an indication of dangerous organic impurity, and may readily be detected by a turbidity it creates when a small quantity of a solution of nitrate of silver (lunar caustic) is added to the suspected water. The hardness of water is due to the presence of inorganic compounds held in solution, of which the principal are the carbonate, sulphate, and chloride of lime and the corresponding salts of magnesium. That portion of such salts which can be precipitated by boiling the water causes what is known as the temporary hardness, and consists chiefly of the carbonate of lime. The permanent hardness is due to the sulphate and chloride of calcium and the magnesian salts, which are not affected by boiling. Hardness is not necessarily a property deleterious to potable water, but such water is very objectionable for washing clothes, for baths, and like domestic uses. It favours also the deposit of earthy and lime compounds on boilers. The amount of hardness in any water may be tested by Clark's soap test, based on the circumstance, which can scarcely fail to be observed by all, that in using soap in hard water a proportion of the soap is always lost in the form of a hard, insoluble curd before any lather will form. The quantity of soap thus wasted by some hard waters is very great, and it thus becomes a matter of much economic importance. One thousand gallons of the Kent Company's water supplied in London from chalk wells destroy 26·5 lbs. of soap, while the Loch Katrine water in Glasgow destroys less than half a pound. The temporary hardness of a water may be effectually removed by a process invented by the late Dr. Clark of Aberdeen, and now used on a large scale in many localities. It consists in adding to the water to be softened a certain proportion—determined by experiment—of quicklime. The lime so added combines with the carbonic acid which holds the carbonates of lime and magnesia in solution, and thereby both

added lime and these original elements of hardness are carried down. *Filtration* is a process carried out both on a public and private scale with the greater part of the water supplied for domestic use. Filter-beds of sand and gravel are used on a large scale, and in domestic filters the substances principally employed are charcoal and spongy iron. (See FILTRATION.) When water is at once excessively soft and impure, it acts on the lead of cisterns in which it is stored, and the lead pipes through which it passes, with dangerous rapidity, and may produce symptoms of lead-poisoning. The water which is supplied to Glasgow, however, although among the softest in use, has not been found to be objectionable on account of its action on lead.

The quantity of water actually consumed in different towns varies within wide limits. The configuration of the town affects the demand somewhat, but the principal cause of variation is the prevalence or absence of water-closets, and the nature of the supply, whether constant at high pressure or intermittent. Glasgow, which enjoys a constant high pressure, and is almost entirely a closeted town, consumes at the rate of nearly 50 gallons per head daily, but by watchful supervision that excessive amount is being gradually much reduced. In many English towns from 20 to 25 gallons per head is found sufficient for all purposes, and in London itself the average supply is not greater. With an intermittent service, domestic store-cisterns become a necessity, and in many positions they are most objectionable, as they absorb noxious vapours, and not rarely they are in direct communication with sewers, and become tainted with gases, and even more palpable filth. The insufficiency of pressure in the case of fires is also a serious objection to the intermittent system. Under a constant high-pressure supply the water to be used is always drawn direct from the street mains, and the only objections to the system are wastefulness, which may be curbed, and the utter collapse of supply when anything goes wrong with the main pipes. Regarding the waste of water, Mr. P. Hawksley, C.E, speaking before the Social Science Association at Liverpool in 1876, makes this remark :—'A well-conditioned service requires less than half the quantity of water that is demanded by an ill-conditioned service. Now the collection of water usually costs £60,000 per million gallons of daily supply, and its conveyance to the point at which its distribution commences will frequently cost as much more, but by way of illustration we will say for the two about £100,000. Assuming then that the careless system requires 40 gallons, when the careful system requires only 20 gallons, we have the following pecuniary results: (1) that the careless system will require an expenditure of £4 per head for collection and conveyance ; (2) that the careful system will require an expenditure of only £2 per head. If we apply these results to a population of 500,000 people, we find that the careless system necessitates an expenditure of £2,000,000 for purposes which can be better and more beneficially accomplished on the careful system by an expenditure of £1,000,000.'

As regards the expense of providing a W.-S., we quote the following statement from the address of Mr. Hawksley, already alluded to :—'To provide a town with water of a suitable quality is now a matter of great difficulty and much expense. Competent and available sources are becoming fewer and fewer, and must in general be sought at distances always becoming more remote. Moreover, the value of land, labour, and materials is almost day by day advancing, and so rapidly and steadily that the present cost of a reservoir is, as I know by repeated experiences, double what it was less than thirty years ago. Indeed, the present average expense of procuring and distributing a gravitation supply of 1,000,000 gallons per day, obtained from a distance of only 10 miles, is rarely less than £160,000, and not very unfrequently even a larger sum. Taking into account the interest on the capital invested, the redemption money, the repairs and maintenance, the rates and taxes, the working expenses, and the incidental disbursements, the cost of 1,000,000 gallons a day, thus obtained, commonly enough amounts to £12,000 a year, and hence the cost of 1000 gallons of water now amounts to nearly 9d. net, whereas in my own bygone days, 4d. or 5d. per 1000 gallons was considered a rather extravagant charge.' This being the experience of one of the most eminent of our modern hydraulic engineers, is sufficient to show that the question of the W.-S. of our great cities may soon become one of the most perplexing and difficult with which municipal authorities have to deal.

Wat'er-Table, in architecture, a projecting stone sloped on the roof to throw off water. It occurs in buttresses and other parts of Gothic architecture.

Wat'ertown, a town of New York, U.S., on the Black River, 3 miles above its debouchement into Lake Ontario, and the junction of several lines of railway. It is supplied with water-power from the Black River, which is here 60 yards wide with a fall of 24 feet. W. has a U.S. arsenal, court-house, several churches, and extensive manufactories of woollen goods, paper, flour, machinery, &c. Pop. (1870) 9336.

Wat'ertown, a town of Wisconsin, U.S., at the junction of the Chicago and N.W. railway, about 40 miles W. of Milwawkee. It contains two seminaries, one Protestant and one Roman Catholic. A large proportion of the inhabitants are German. Pop. (1870) 5364.

Wat'erville, a small town of Maine, U.S., on the Maine Central railway and Kennebec river, 18 miles N.W. of Augusta. It has several churches, a college, cotton-mills, and door, sash, and blind factories. Pop. (1870) 4852.

Wat'er Vi'olet. See HOTTONIA.

Wat'ery Gripes is a popular designation for a form of serous diarrhœa, occurring in infants, the discharges being copious, thin, watery, often nearly colourless, and occasionally intermixed with flakes or shreds. Owing to the severity of the symptoms, and the rapidity of action, the disease is sometimes called *cholera infantium*, and there is some reason for the designation, as the malady is very dangerous, and often rapidly fatal. W. G. may be caused by sudden impressions of cold on the surface, or by cold drinks taken when the body is heated, and also by exposure to air contaminated with the products of decomposition. The first thing to do in a case of infantile diarrhœa is to produce evacuation of the bowels by means of a small dose of castor-oil with a few drops of tincture of opium, and the child should be wrapped up in warm flannel, and hot flannel cloths should be kept constantly applied over the abdomen. A few grains of Dover's powder, or aromatic powder of chalk and opium, according to the age of the child, may be given. Extract of hæmatoxylon is probably the best astringent that can be given, and tincture of red gum is also serviceable.

Wat'ford, a market-town of Hertfordshire, England, on the Colne, 17½ miles N.W. of London by rail, has two churches, St. Mary's (restored 1848–71, at a cost of £11,000), with a spire 100 feet high, and St. Andrew's (1858), in Early English style. Other buildings are the Public Library and School of Science and Art (1874), Masonic Hall (1873), the London Orphan Asylum (for 350 boys and 200 girls), the almshouses of the Salters' Company (1864) and of the late Countess of Essex (1876), eight schools, &c. A silk factory, iron-foundry, and three breweries, form with malt-kilns and corn-mills the chief industrial establishments of W., which publishes one weekly newspaper, and had a pop. (1871) of 7481.

Wat'kin, Sir Edward William, the son of a merchant, was born in Manchester, 1815, became a partner with his father, and entered on a career of public usefulness. He was an advocate of free-trade from the beginning of the Anti-Corn-Law movement to its triumph in 1846, organised the great literary soirees of the Manchester Athenæum presided over by Dickens, Disraeli, and Talfourd in 1843–45, was mainly instrumental in opening the 'Queen's,' 'Peel,' and 'Philip's' parks, was one of the originators of the *Manchester Examiner*, and took an active part in bringing about the confederation of the Canadian Dominion and the adoption of the Intercolonial Railway scheme. He was made a baronet in 1868. A prominent representative of the railway interest both in England and in Canada, and a pronounced Liberal in politics, he sat for Stockport 1864–68, and was returned for Hythe and Folkstone in 1874.

Wat'ling Island. See BAHAMAS.

Wat'son, Richard, an English prelate, born at Heversham, Westmoreland, in August 1737, from the grammar-school of his birthplace was elected to a sizarship of Trinity College, Cambridge (1754), where he became a fellow (1760). Knowing nothing of science, he was raised to the chemical chair (1764), but exchanged it in seven years' time for that of divinity, and the latter he retained as well as a prebend and the archdeaconry of Ely, when in 1782 he was advanced to the bishopric of Llandaff. Himself of doubt-

ful orthodoxy, he combated the views of Gibbon and Paine in his *Apology for Christianity* (1771) and *Apology for the Bible* (1796), other works by him being *Chemical Essays* (5 vols. 1781-87; 7th ed. 1800), *Sermons on Public Occasions* (1788), and *Miscellaneous Tracts* (2 vols. 1815). He died at Calgarth Park, in Westmoreland, 4th July 1816. See his autobiographical *Anecdotes of the Life of R. W.* (Lond 1817).

Watt, James, was born at Greenock, Scotland, January 19, 1736. He early displayed a strong love for mathematical and especially mechanical science, and at the age of eighteen was apprenticed to a mathematical instrument maker in London. After a year's stay there, however, he was obliged on account of bad health to return home. In 1757 he started business in Glasgow as a mathematical instrument maker; but, though patronised by the university and occupying premises within its precincts, he was just able to make ends meet. In 1763 he set up as a general engineer, and soon acquired a high reputation. In 1767 he was employed as surveyor and general valuator for the projected Forth and Clyde canal, and from this time his fame as an engineer steadily grew. W. improved the harbours of Ayr, Port-Glasgow, and Greenock, formed plans for the deepening of various rivers, and projected the Caledonian Canal. For his survey work he introduced many improvements in the construction of instruments; but these, though fully evincing his singular inventive genius, sink into insignificance beside the great additions which he made to our knowledge of steam and its properties as a motive power. The years during which he wrought as instrument maker to the university he had profitably employed in self-culture, and as early as 1759, at the suggestion of Robison, afterwards Professor of Natural Philosophy in Edinburgh University, his attention had been directed to steam as an effectual working power. In 1764, while repairing a working model of Newcomen's engine which belonged to the university, he saw at once in what directions improvements were necessary so as to prevent the great waste of energy which was inevitable. He determined to remedy this great defect, and effected his object in 1765 by the invention of the separate condenser (see STEAM-ENGINE). The utilisation of the expansive force of steam to effect both the down and up stroke of the piston completed his great improvements, though the subsequent inventions of the eccentric crank and parallel motion would of themselves entitle him to a first place among inventors. His first arrangements with Roebuck of the Carron Iron Works for the construction of steam-engines were put an end to by the failure of the latter, but in 1773 he entered into partnership with Boulton of Soho, Birmingham. He had taken out his patent in 1769, and in 1775, when the firm of Boulton & Watt began to construct engines, he got his patent prolonged for twenty-five years. He retired from business in 1800, and died at Heathfield, Staffordshire, August 25, 1819. W. was a fellow of the Royal Societies of London and Edinburgh, and a foreign member of the Institute of France. Though known best as inventor and engineer, in the more theoretical departments of science he was quite at home, and was an independent discoverer of the composition of water, though Cavendish had the priority (see WATER). See Muirhead's *Mechanical Inventions of J. W.* (2d ed. 3 vols. 1859), and Smiles' *Lives of Boulton and W.* (Lond. 1865).

Watteau, Antoine, the celebrated French 'pastoral' painter, was born at Valenciennes in October 1684, and after studying art in his native town removed in 1704 to Paris, where his work as a decorative painter attracted the notice of Gillot. Apt and indefatigable, he greatly improved by study of the works at the Luxembourg, especially those of Rubens, and outvieing Gillot in popularity, he was made a member of the Academy in 1717, and subsequently *Peintre de Fêtes Galantes* to Louis XIV. His subjects were such as may be implied from the later title—rural groups, *fêtes champêtres*, idylls in court dress, serenading scenes, and all that has gone to make his name a synonym for the pseudo-pastoral, and has gained for spurious romance in landscape the designation of *à la W.* Representing fairly the general spirit of the age, in which they then obtained a high reputation for the artist, his works are characterised by freedom and fluency, neatness and spirit, a piquant jauntiness of motive, and a pleasing tone of colour. They are numerous and widely scattered; the finest collection is at the Louvre. On account of ill-health W. visited England in 1720, and after remaining there for two years returned to Paris and died at Nogent, 21st July 1721. He had many imitators, but even Greuze, the most successful, fell far short of the brilliant espiégelrie of the master. A good idea of W.'s art may be gained from *Figures de Différents Caractères de Paysages et d'Études Dessinées d'Après Nature par A. W.* (2 vols. with 350 plates, Par.); *The Ornamental Designs of W.* (10 vols. of lithographed plates, Lond. 1840 *et seq.*); Goncourt's *Catalogue Raisonné de l'Œuvres de W.* (Par. 1876); and *Twenty-six Drawings by W., reproduced from the Original Works* (Arundel Society (1878).

Wattle, an Australian colonial name for a species of Acacia (q. v.).

Wattle-Bird (*Anthrochæra carunculata*), a species of Australian *Meliphagidæ* or honey-eaters, attaining the size of a magpie, and coloured of a greyish-brown hue. It possesses a curious appendage of reddish colour depending from each side of the throat, and from this structure the bird derives its popular cognomen. The food consists of honey and flower-juices.

Wattled and Combed. See BARBED.

Watts, Isaac, D.D., was born at Southampton, 17th July 1674. He studied at a Nonconformist academy at Newington, London, was then appointed (1698) assistant clergyman to the congregation worshipping in Mark Lane, some years after (1702) sole pastor of the same body. Obliged through bodily weakness to resign his charge (1712), he spent the rest of his life at the family seat of Sir Thomas Abney, Abney Park, near London. He died 25th November 1748. W. wrote *Hymns and Spiritual Songs* (1707), *Divine and Moral Songs for the Use of Children* (1720), *A Manual of Logic* (1725), several volumes of *Sermons*, besides other works of less note. As a religious poet W. has been always widely popular. His hymns are marked by religious fervour and evangelical zeal. Widely separated parties have used them as manuals of Christian devotion, and they have come home to the heart of the English common people in a way that no other devotional lyrics, not even Wesley's or Cowper's, have done. The *Logic* of W. was for long a widely popular book. Though not distinguished by profound metaphysical thought, it is yet a very able treatise. It is plain and practical, vigorous and sensible, and may even yet be read with profit. The works of W. were published in a collected form first in six then in nine vols. (Lond. 1810–12). See the Biographies of Milner, Southey, Palmer, Gibbons, and Hood (Lond. 1875).

Waugh, Edwin, was born at Rochdale, 29th January 1817, and worked in a bookseller's shop until the age of thirty. He was then appointed secretary to the Lancashire Public School Association, with which he was connected for nearly five years. His first productions of any note were published in the *Manchester Examiner* in 1846-47. His first song, 'Come whoam to thy childer and me,' appeared in that paper in 1855, and became as popular in the N. of England as some of Burns' songs in the W. of Scotland. Other works of W.'s are *Lancashire Sketches*, *Poems and Lancashire Songs*, *Factory Folk during the Cotton Famine*, *Rambles in the Lake Country*, *Tufts of Heather*, *Besom Ben*, *The Old Blanket*, *Jannock, or the Bold Trencherman*, *Old Cronies*, *The Barrel Organ*, *Rambles and Reveries*, *The Chimney Corner*, *Up the Rhine*, &c. W. is a genuine and original poet and humorist; and his best productions will always be read with delight, particularly in Lancashire.

Wauke'gan, a city of Illinois, U.S., on a bluff overlooking Lake Michigan, 35 miles N. of Chicago by rail. It has 9 churches, 2 weekly newspapers, carriage factories, machine-shops, tanneries, &c., but is chiefly important as a pleasure resort. It has valuable mineral springs. Many Chicago merchants reside here. Pop. (1876) 6000.

Waves. In its most general sense, a wave consists of the propagation of a particular configuration or state of strain through a system of particles or other material medium. Thus, if we observe what goes on in a substance at a given place and immediately transport ourselves forward in the direction of propagation of the wave, then after a definite interval of time we shall observe the same things occurring in the same order at the new place. The sequence of changes which was observed in both cases was caused by the passage of the wave, which similarly affected all places intermediate to the places at which the observations were made. Since a wave, then, consists of the propagation of a state of strain, there must have been stress applied originally to pro-

duce the strain, while the strain itself travels because of the elasticity of the medium. The portion strained by the direct application of the stress recovers itself and passes on the strain to the contiguous portion, which also recovers by reason of its elasticity, and acts similarly upon the next portion. Consider, for instance, the propagation of ripples over the surface of a still sheet of water when a stone or other body is dropped into it. The liquid immediately beneath the stone is forced down, and, as water is practically incompressible, this necessitates the rising of liquid all round the stone. This raised ring of liquid, however, at once descends by its own weight, simultaneously pushing up the next cylindric column which borders on it; and in this way a growing circular wave is propagated from the point of original disturbance as centre over the surface of the water. If the attention is fixed upon any one point of the surface, this point will be observed to rise and fall with an approximately simple harmonic motion as the wave travels past it. This oscillatory or vibratory motion is a characteristic of all the simpler cases of wave-motion with which we are acquainted; and even in more complex cases a certain periodicity in the motion of each elementary portion of the substance is observable as wave after wave of the same type passes through it. The distance from crest to crest of such successive W., or more generally the distance between any two successive elements which are passing through the same phase of their periodic motion, is called the *length* of the wave; and this length divided by the periodic time of the wave. *i.e.*, the time during which any element passes through its periodic changes, is called the velocity of the wave. For example, the velocity with which a wave travels along a stretched inextensible string of length l, mass m, and tension T, is given by the formula $\sqrt{\frac{Tl}{m}}$. A neat and elementary though indirect proof of this is given in Thomson and Tait's *Elements of Natural Philosophy*, vol. i.

A very important class of W. is that which includes W. of compression and dilatation, which are familiar in the atmospheric W. which constitute sound. Suppose, for definiteness, a tuning-fork to be sounding at the mouth of a long tube filled with air or other gas. Then with every vibration of the prong, a *crest* of condensation followed by a *trough* of rarefaction is sent along the air in the tube. If there is no loss of energy throughout the operation, every particle of air, however distant, will be set into to-and-fro vibrations of exactly the same period as the vibrations of the tuning-fork. It is evident, however, that the phase of each particle at any given instant will depend upon its distance from the end of the tube. Thus, as a wave passes along the tube each particle of air vibrates to-and-fro through, in general, a very small space about its mean position. A particle a little further on performs the same motion precisely, except that it passes through its mean position a little later; and hence, according to the relations of phase at any instant, the two contiguous particles will be either approaching or receding from each other. If we then consider any narrow segment of air bounded by two contiguous normal sections, this elementary volume will be subject to a periodical compression and dilatation accompanied by a simultaneous to-and-fro vibratory motion of the same period. If we assume that Hooke's Law of Elasticity holds for sudden compression of air, the velocity of a sound-wave is found to be $\sqrt{\frac{p}{\rho}}$ where p is the pressure and the ρ density of the air. This value when calculated is found not to agree with experiment, but when allowance is made for the thermal relations of gases, as was first done by Laplace, the reason of the discrepancy is made apparent (see SOUND).

Take now the case of W. in liquids. Of these there are several species. There are W. of compression, such as sound W. in water, which are similar in character to atmospheric sound W., but which travel much faster. Then there is the *long* or *solitary* wave, whose length is great compared to the depth of water. Such are the tidal wave, and the long wave which accompanies a canal-boat. Its main characteristic is that the horizontal disturbance is the same at all depths, while the difference of pressure on the ends of any small horizontal element is due to the difference of level at the surface. The velocity of the wave depends only on the depth, being equal theoretically to the velocity which a stone would acquire in falling through a height equal to half the depth of the water. The case of *oscillatory* W. falls next to be considered, and amongst these are included all W. whose lengths are small compared to the depth of the liquid, from the long mid-ocean roller to the smallest ripple on a pool. If the depth is infinite compared to the wave-length, each particle of liquid describes a *circle* about its mean position, a circle whose radius diminishes rapidly as the depth increases. Thus at a depth equal to a wave-length the disturbance is on $\frac{1}{535}$th of that at the surface. Consequently storm W. agitate the ocean to a comparatively small depth. The velocity of such W. to a first approximation is given by the formula $\sqrt{\frac{gl}{2\pi}}$, where g is the acceleration due to gravity, l the length of the wave, and π the ratio of the circumference of a circle to the diameter, so that the wave moves slower the shorter it becomes. If, however, the wave is very small, surface tension must be taken into account, and then as the wave diminishes the velocity increases, becoming infinite when the length vanishes. Here we have the distinction between an ordinary wave, which runs mainly by gravity, and a ripple, which runs mainly by surface tension—the longer the wave the faster it runs; the ripple runs faster the shorter it is. Hence there must be a wave intermediate in character to these two types, the velocity of which is a minimum. As sea W. approach a shelving beach they alter their character and act more as long waves, whose velocity, as we saw above, diminishes with the depth. Hence such a wave coming in from the sea is travelling faster than its circumstances admit of. Consequently there is resistance offered to its progress, the base is retarded, while the crest, advancing by its own momentum, curls over in the manner characteristic of all *breakers*. The propagation of W. through elastic solids is the last case which calls for mention. This, however, is a subject of much higher difficulty than the preceding, and no general solution has yet been given. Its physical importance arises from the fact that the transmission of light through the ether seems to belong to this class of problems. Neumann, Maccullagh, Stokes, and others have discussed it in various aspects, but our present analytical methods are not sufficient for its solution. See UNDULATORY THEORY.

Wavre, a town of Belgium, province of Brabant, on the Dyle, 15 miles N.W. of Louvain by rail. It carries on brewing, dyeing, and the manufacture of cottons and paper. Pop. (1874) 6553. Near W. the Prussians under Thielemann defeated (June 18, 1815) the French under Grouchy, who was thus hindered from coming to the aid of Napoleon at Waterloo.—**W.** or **Wawer**, a village of Russian Poland, government of Warsaw, on the Vistula, 9 miles N. of Warsaw, the scene of bloody battles between the Poles and the Russians under Chlopicki on the 19–20th February 1831, and again on the 31st March, the latter resulting in favour of the Poles.

Wax, a name given to various animal and vegetable substances having analogous physical peculiarities, but differing somewhat in chemical constitution and in other properties. They are all hydrocarbon compounds allied to oils and fats, but common W. differs from the ordinary fats in containing no glycerine. In addition to bees' W., which is the variety commonly indicated when the term is used, the following substances are known under the name of W.:—*Chinese W.*, or *Pela*, a body obtained by the puncture of the branches of certain trees by an insect, *Coccus pela*, allied to the insect which similarly produces cochineal. Pela is a hard, glistening, white, semi-crystalline solid, resembling spermaceti, and fuses at 179·6° F. It is composed principally of cerotin, the principal constituent of bees' W. *Japanese W.* is a hard, whitish, fatty substance, said to be obtained from the *Rhus succedanea*. It melts at 107·6° F. *Carnahuba W.* is a product from the leaves of the palm, *Corypha cerifera*, growing in Brazil. It is of a greenish-white colour, excessively hard, and fuses only at 182·3° F. *Palm W.* is a closely-allied product obtained from the palm, *Ceroxylon andicola*, of S. America. Its fusing-point is about the same as that of Carnahuba W. *Myrtle W.* is obtained from the berries of *Myrica cerifera*, and other species growing principally in the United States, but also in Cape Colony. It forms a greenish-coloured, hard, solid substance.

Common W., which forms the honeycomb of the various species of bees, is in its unbleached condition a hard unctuous solid, possessing usually a faint sweetish odour, but no taste. It is easily separated from the extraneous matter of the comb by melting in water, when the W. floats on the surface of the water as a thin, oily fluid, which is drawn off and allowed to solidify into

cakes. A large amount of unbleached W. from almost all regions is annually imported into the United Kingdom. The preparation of purified or White W. (*Cera alba*) is accomplished by exposing the substance in very thin flakes or shreds to the influence of the atmosphere and light, the W. being periodically watered and turned, as is done in the case of grass-bleaching of linen, &c. When the whole of the surface colour has disappeared the W. is re-melted, and a new surface is thereby obtained for exposure, and the treatment is thus continued till a uniform white colour is obtained throughout the mass. W. may also be bleached by the use of bleaching powder and other chemical agents, but the process is objectionable, because it not only injures the material, but in the case of bleaching powder the whole of the chlorine is not removed; and when the W. so treated is used for burning, irritating and deleterious fumes of hydrochloric acid are given off. Pure white W. consists to the extent of nearly 80 per cent. of cerotin, soluble in boiling alcohol, with nearly 20 per cent. of an insoluble waxy substance called myricin, and a small proportion of cerolein, which gives hardness to the mass. It is semitransparent, tasteless, and inodorous, softening so as to admit of being moulded by the fingers at 85° F., and melting at 145° F. It is chiefly used for making candles of unequalled beauty and illuminating effect, for modelling and making wax flowers and fruits. *Medicinally*, White W. has emollient properties, and is chiefly employed in medicine as an ingredient in ointments and in the preparation of simple ointment. Yellow W. is also used as an ingredient of plasters and ointments. Owing to its high price, white W. is much adulterated with spermaceti and inferior waxes, and even with starch, &c.

Wax, Min'eral, a popular name for certain fossil hydro-carbons, which occur in small quantities chiefly in the Carboniferous formation. The most familiarly known variety of M. W., viz. ozokerit, has been used for the manufacture of candles, which are of a shining black colour, unless purified by a complicated process. Preparations of a similar nature are now employed, especially in America, as a basis for medicinal ointments, and are sold under the names of ozokerine, vaseline, &c. They possess a great advantage for this purpose over lard, from their non-liability to turn rancid.

Wax-Cloth, a popular name for oil-cloth or Floor-Cloth (q.v.).

Wax Flowers. The manufacture of W. F. and fruit is peculiarly a British industry. Thin sheets of bleached or coloured bees' wax are used for leaves and petals, and wire covered with cloth for stems. The leaves are curled by means of metal or ivory 'pins,' and variegated tints are brought up with dry colours. W. F. are more easily made than flowers of cambric, &c. (see FLOWERS, ARTIFICIAL). Fruit is modelled hollow by means of moulds of plaster-of-Paris or other composition. A very pure kind of paraffin has of late years been successfully substituted for bees' wax in modelling. Owing to their fragility W. F. are chiefly employed as table ornaments. and not for toilet purposes.

Wax Insect, the name given to various insects that secrete wax. In the Bee (q. v.) the wax-secreting glands appear to consist of special modifications of dermal or skin glands. The Hemipterous family *Coccidæ* includes the chief wax insects, familiarly known as bark lice. They inhabit the bark of trees and shrubs, one species, *Coccus cacti* of Mexico, being the species which affords *Cochineal* (q. v.). *Coccus sinensis* is a W. I. inhabiting a kind of sumach-tree (*Rhus succedaneum*), the wax secretion being gathered from the branches on which it is deposited.

Wax Myr'tle. See CANDLEBERRY.

Wax Paint'ing, another name for Encaustic Painting (q. v.).

Wax Palm of New Granada is *Ceroxylon andicola*, a tall elegant palm with a whitish stem attaining 190 feet, and surmounted by a tuft of pinnate leaves, each 20 feet long. It is remarkable amongst *Palmæ* from the altitude at which it grows. Humboldt first discovered it at the foot of the snow-clad volcano of Tolima in the central Cordillera, and it grows in abundance at an elevation between 6500 and 9700 feet in N. lat. 4° 35'. The trunk is annulate, covered all over with a thin coating of a whitish substance, which is scraped off, mixed with tallow, and made into candles. It consists of vegetable wax, and a crystalline resin called *Ceroxylin*. For the W. P. of Brazil see CARNAHABA, and consult article PALMS.

Wax Sculp'ture was known to the Greeks and Romans, and was much practised by the Italian artists of the Renaissance. Portrait medallions in wax placed on a ground of coloured ivory or other material were fashionable in Italy and Germany during the 16th and 17th centuries. The 'waste wax' (*cire perdu*) process of casting bronze, which is still in use, is very ancient. A core of baked clay and other substances presenting the general contour of the object to be produced is covered with a layer of wax, which is worked by the sculptor into all the details of a finished work. Rods of wax are then placed where required for air-ducts, and the whole surface is carefully covered with fine liquid plaster on which a thick coam is afterwards laid. The work is then exposed to heat, to run out the wax from between the core and external mould. This having been effected and the surfaces dried, molten bronze is run into the vacant space, and a facsimile in metal of the sculptured wax thereby obtained. The process is hazardous, for should the casting be faulty the artist's long labour is lost.

Wax Tree (*Vismia*), a genus of *Hypericaceæ*, in which some of the tropical American species yield a copious supply of the yellow resinous juice characteristic of the order. This gum-resin so much resembles gamboge in appearance that it is called American gamboge: it possesses like purgative properties.

Wax'wing (*Ampelis garrula*), a species of *Insessorial* birds belonging to the *Dentirostral* group. It is also known as the Bohemian Chatterer. It derives its name from the red wax-like appendages attached to the secondary and tertiary quills of the wing. The bird attains a length of 4 or 5 inches. Its plumage is greyish brown, with darker markings, and the head bears a crest of orange-brown feathers. The W. occurs in England, and migrates southwards in winter. The food consists chiefly of berries and other fruits. The American W., or Cedar Bird, is the *Ampelis cedrorum* of ornithologists. It is crested like its Old-World namesake. Its colour is a reddish olive above, shaded with grey, a yellowish hue prevailing on the under parts.

Waxwing.

Wax'y Degenera'tion. See AMYLOID DEGENERATION.

Way'land the Smith (Old Eng. *Weland*, Old Norse *Völundr*, Old High Ger. *Wiolant*, Mod. Ger. *Wieland*), a mythical Teutonic hero, who in the Edda-lay *Völundar-kvida* appears with his brothers Slagfidr and Egil, sons of the king of the Finns. The brothers went on snow-shoes to hunt, and came to Wolfdale, where they built a house by Wolf Lake. Early one morning they found three fair maidens sitting on the border of the lake and spinning flax, with swan plumages lying beside them. The brothers induced them to go to their dwelling. Egil had Olrun, Slagfidr had Swanwhite, and W. had Allwhite. After they had lived together seven years, the maidens, who were indeed Valkyrjur (q. v.), flew away, seeking battles, and did not return. Egil and Slagfidr went in search of their wives, but W. remained in Wolfdale, busied with smith's work, setting precious stones in gold and making splendid rings to present to his Allwhite when she should return. Nidud, king of the Niars, came to W.'s house, and overpowering him while he slept, carried him off and confined him on Söstadholm, where he was forced to make all manner of jewels for the king. But seizing his opportunity, he killed Nidud's two sons and dishonoured his daughter Bödvild, after which he flew away on a swan's plumage he had contrived. This story may be compared with the numerous tales of swan-maidens in Teutonic mythology, and with the Greek myths of Dædalus and Hephæstus.

The name of W. is still preserved at a place in Berkshire called 'Waylandsmith's Cave,' the popular tradition concerning which Scott made use of in *Kenilworth*. It stands at the foot of the White Horse, and is a megalithic monument, consisting of two chambers constructed of upright stones and roofed with large slabs, called 'Welandes Smidde' in the *Codex Diplom.*, No. 1172. See Grimm, *Deutsche Mythologie*, and *Heldensage*; Scott, *Kenilworth*, chap. xiii. and note; G. B. Depping and F. Michel,

Véland le Forgéron, Dissertation sur une Tradition du Moyen Âge, avec les Textes Islandais, Anglo-Saxon, Anglais, Allemand, et Français-Roman (Par. 1833; Eng. trans., with additions by S. W. Singer, Lond. 1847).

Wayne, Anthony, an American general, was born at East Town, Pennsylvania, January 1, 1745, and became a land-surveyor. He was an intimate friend of Franklin, and took an active interest in public affairs. Having married and settled to farming (1767), he was elected to Pennsylvania convention and legislature in 1774, served on the committee of safety, and in 1775 raised a regiment with which he took part in the campaign against Canada. He fought with distinction and was wounded at the battle of Trois Rivières (January 3, 1776), held the fortress of Ticonderoga and Mount Independence till May 1777, and, after receiving the commission of brigadier-general, led a division at Brandywine (September 11), and commanded the right wing at Germantown (October 4). He made a dashing raid on the British lines in the winter of 1777-78, carrying off a great quantity of supplies, and on the night of 15th July 1779 achieved the most brilliant of the American victories in the storming of Stony Point (q. v.), for which he received a gold medal and the thanks of Congress. By a bayonet-charge he rescued La Fayette in Virginia in 1782, made a daring attack on the whole British army at Green Spring (July 6), and defeated the British and Indians in Georgia. After the war 'mad Anthony' retired quietly to his farm, but he was made major-general in 1792, and again took the field, this time against the Western Indians, whom he overthrew at Maumee Rapids, and forced to conclude the Treaty of Greenville (1795). On his way back to his farm at Waynesborough, he died at Presque Isle (now Erie), 15th December 1796. See Life by General J. Armstrong (Spark's Series). A monument was erected to him at Waynesborough in 1809.

Ways and Means, Committee of. See PARLIAMENT.

Wazi'ris (the children of Wazir or Vizier), a tribe of independent Afghans, who occupy the Suleiman Mountains, on the W. frontier of the Punjaub, British India. It is estimated that they can furnish 44,000 fighting men. Some of them have settled quietly within British territory, chiefly in the district of Bunnu, where they cultivate 27,000 acres and pay a revenue of £900. The majority yet live in the hills, a terror to all their neighbours, especially to the caravans that traverse the Gomul pass. Their crops are wheat, maize, and barley; they rear horses and sheep, and export iron and wood.

Weal'den Forma'tion, a series of freshwater beds which, in the geological scale, intervene between the Upper Oolite and the true Chalk. The W. F. derives its name from the circumstance that it is typically displayed, and was originally investigated, in that part of the south-eastern counties of England known as the 'Weald.' The great interest attached to the W. F. rests on the fact, first pointed out by Dr. Mantell, that, though occupying a position between typically marine strata, it is undoubtedly of fluviatile origin. In it the Belemnites, Ammonites, &c., of the Chalk and Oolite are all wanting, but we find instead the bones of huge reptiles, freshwater shells, plant-remains, and other vestiges of the fauna and flora of the shores of the Cretaceous Sea. Of the Reptilian remains, the most remarkable are perhaps those of the Iguanodon, a gigantic animal first detected by Dr. Mantell in the sandstones of Tilgate Forest. It probably attained a length of 60 or 70 feet, and from its crenated teeth and other characters appears to have been allied to the hideous little iguanas which inhabit the tropical parts of the New World. Among the shells, the genera Paludina, Melania, and Cyrena are conspicuous, and large quantities of a species of the first named of these produce the hard limestone known as 'Sussex marble.' Cypris and other well-known forms (of Entomostraca are very common. Of the Wealden plants, Conifers, Cycads, and Ferns are especially abundant. The W. F. is divided into two groups, an Upper, or Wealden Clay, and a lower, called the Hastings Sand; the united thickness of the two being probably about 2000 feet. The exact area occupied by the W. F. is not very accurately known. Besides the typical locality in the S E. counties, it is exposed in Dorset, in the Isle of Wight, and also appears in France, Westphalia, and Hanover; and the whole of this extensive area is supposed to have been occupied by an enormous river-delta.

Wealth. See CAPITAL.

Wean'ing, and Feed'ing in In'fancy. The separation of the child from the mother necessarily involves a crisis in its existence, and is attended with more or less constitutional disturbance. When the state of health of both mother and child is favourable, it has to be determined what is the proper time for W. As a purely physiological question it must be evident that there is a definite time at which it is proper for the well-being of both mother and child that the latter should enter upon an independent period of existence. It has frequently been asserted that the natural period for W. is on the completion of the process of dentition; but as dentition is not completed till about the close of the second year, the period of suckling is much too long; for the milk secreted ceases long before that time to be sufficient for the nourishment of the child. Indeed, owing to deficiency in the quantity and quality of the milk in relation to the wants of a healthy, vigorous child, the cases are exceptional in which a woman is able to suckle her child, without assistance in the way of extra aliment, for a longer period than ten months; and a large proportion of mothers require supplementary aid much sooner. When the mother, or nurse, is healthy and vigorous, the child should have nothing but what is obtained from the breast for the first six or seven months. A partial failure in the quantity or quality of the milk may occur at a much earlier period, so that it may be necessary even at the second or third month partially to feed while nursing is going on.

No definite time, as to months, can be fixed at which the child should be weaned; but, as a general rule, it should be from the seventh to the twelfth month, and certainly not later than the latter period. In all cases it is advisable to accustom the infant to other food before W.; otherwise the process is much more troublesome. The quantity of milk should be gradually and steadily diminished, and the proportion of other nutriment should be steadily increased until the latter alone remains. If the W. process be thus conducted, a minimum amount of discomfort will follow, and the screaming fits will not last beyond a couple of days. Discomfort may be obviated, in the case of the mother, by saline laxatives, abstinence from fluids, and the application of belladonna, or cooling lotions, to the breasts. The period of W. should be determined to some extent by the state of the child's health, and the process should be delayed until the subsidence of a febrile attack, or of an ordinary catarrh, and during the constitutional disturbance attending dentition. In the case of a perfectly healthy child, and an average result in the eruption of the teeth, the age of about ten months is indicated as the proper period for W., as there is usually a pause in the process of dentition subsequent to the appearance of the eight incisor teeth.

Every mother should be encouraged to nurse her own offspring, unless under exceptional circumstances, such as a deficiency in the quality and quantity of the secretion; abnormal conditions of the nipples rendering suckling difficult; excoriated and chapped nipples; inflammation and suppuration of the mammary gland. In some instances there are constitutional reasons why a mother should never nurse her children, as in cases of phthisis, epilepsy, great constitutional weakness, and nervous excitability. Amongst those in whom there is a hereditary tendency to insanity, an attack of acute mania may be set up by lactation. Whether the infant is brought up at the breast. or by artificially-supplied food, it should be supplied with nourishment at regular intervals, say every four hours, and not when the child begins to cry and becomes restless.

When it is determined that the mother cannot suckle her child, a wet-nurse should be selected, or artificial food must be given, but a wet-nurse is preferable. If a wet nurse cannot be afforded or procured, the infant must be provided with such nourishment as may, chemically and otherwise, most nearly resemble that which nature provides. Asses' or goats' milk may be preferred as nearest in composition to human milk; but the milk of the cow is generally the only kind available. Cows' milk is richer than the human in the corpuscular element, and if given undiluted to a young infant it generally produces some form of gastro-intestinal disorder. If rich and pure, an equal bulk, or even more, of water may be added; but milk supplied in towns being generally previously diluted, not more than a third of added water is necessary. A little ordinary sugar, or, better still, sugar-of-milk, should be added, and the mixture should always be given warm, or about blood-heat.

If at all practicable, it is best to obtain the milk for an infant from one cow. For the first three months milk and milk alone is the best as well as the most natural food for the child; but the safest indications for supplemental diet is in the condition of the child or of the nurse. When a child is brought up on the bottle, it is necessary that the strictest attention should be paid to cleanliness; for if the apparatus is not kept scrupulously clean, small particles of curd are apt to accumulate within it or the tube; and these, if swallowed by the infant, are apt to excite gastric or intestinal disturbance. The best kind of feeding-bottle is that with a valve in connection with the tube, as the tube is thereby always kept full, and less power of suction is required by a weak, delicate child.

Many substances have been recommended as substitutes for or supplementary to milk in the alimentation of infants, and none more highly than Baron Liebig's *Food for Infants*, which was devised as the result of much original research. Nothing is better than rusks of good quality; and, if well made, they require no boiling, but are to be covered for a minute or two with boiling water, which is then poured off, and milk or cream, with a very little sugar, added before it is broken up. When the child grows older, a little chicken soup or beef-tea may be given twice a week; and an approach should be gradually made to the ordinary diet of childhood.

Wea'sel (*Mustela vulgaris*), a species of *Carnivorous* Mammalia, belonging to the *Semi-plantigrade* section of the order, or that in which the sole of the foot is only partially applied to the ground in walking. In each jaw there are eight premolar teeth, and five toes on each foot. The W. is one of the best-known British quadrupeds. It attains a length of from 11 to 12 inches, has a bright brown fur above, but is white beneath. In winter the fur assumes a lighter tint, and instances are on record in which a white colour has occurred in the winter fur. The animal is extremely carnivorous. It attacks rabbits, hares, and birds of all kinds, and is specially fond of eggs. It seizes on the neck of its victim, and appears to wound the large blood-vessels, and thus to drain the body of its blood. The W. readily attacks the dog when brought to bay, and fights with a tenacity astonishing in an animal of its size. The young number from four to five. The W. has its home in some secure situation in a dark or wooded place.

Weath'er is the state of the atmosphere at any time and place as regards its temperature, pressure, humidity, electrification, and motions. Whatever may change any or all of these tends to alter the W., though the changes may not be sufficient to destroy the balance of affairs, so that the W. really undergoes little alteration. The great source of all variations of W. is, then, the sun, taken in conjunction with the earth's diurnal and annual movements. A temperature variation is necessarily accompanied by a pressure variation, and that again generates currents (see WINDS), which, in the endeavour to restore atmospheric equilibrium, bring about the various meteorological changes which are considered under CLOUDS, HAIL, RAIN, SNOW, THUNDER, &c. In temperate latitudes, where these various W. factors are much affected by purely local conditions, it is impossible to predict what the W. will be more than two or three days in advance. From accumulated observations, it is possible to say what the *general* character of the W. will be; such, for instance, as the assertion that the W. will be broken during the equinoxes; but to specify what the state of the atmosphere on a particular day will be is a hopeless task. A careful study of meteorological conditions in the neighbourhood of a given place, such as may be obtained from the daily charts now published by the Meteorological Office, are, however, valuable as indicating if a change of W. is probable, and if so, of what nature it will most likely be, during the next few days. In tropical regions the W. is very constant, undergoing great changes only at special times of the year, if we except occasional storms which sometimes arise. The average annual W. is a good indication of the nature of the Climate (q. v.) at any locality. The necessary instruments for a complete determination of the W. are the thermometer for temperature, the barometer for pressure, the hygrometer for humidity, the electrometer for electrification, and the W.-cock and anemometer for wind measurements. To these should also be added the chemical apparatus for estimating the quantity of ozone, and of the various impurities which ordinarily abound in the atmosphere.

Wea'ver Bird, a name given to certain species of *Insessorial* birds, allied to the conirostral finches. The *Ploceus Taha*, or Taha W. B., is one of the best known. It is of a brownish-yellow colour, variegated with black and grey. The Sociable W. B. (*Philetærus socius*), inhabiting S. Africa, takes its name from its habit of building its nest beneath a common roof. The average length of this species is five inches, and its colour is mainly brown. The Red-necked W. B. (*Hyphantornis textor*) is found in Cingo and Senegal, and has a red collar round the neck. The average length is six inches, and the prevailing colour is orange yellow. The Red-billed W. B. (*Textor erythorhynchus*) occurs in S. Africa, and has a dark-brown plumage, a blackish head, and a crimson bill. It is often seen in Britain as a cage-bird, breeds in confinement, and seems to thrive well. The nests of the Weaver birds exhibit great variation. Some hang from the branches of trees, and are so placed that monkeys and other enemies find access difficult or impossible.

Wea'ving is the art of manufacturing textile fabrics by means of intersecting yarn or thread, previously prepared by spinning. The operation is performed in a loom, the yarn being of two kinds, the warp yarn, which constitutes the web in the loom, and the weft yarn, which crosses the warp, and is arranged on 'spools' or 'pirns' and thrown across the web in a shuttle or shuttles. The art is one of the most ancient and important of all human industries, and it has exercised an influence on the social and material condition of the race not equalled by any other manufacturing art. It is further scarcely too much to say that from its first beginnings till now the art of W. has been progressively improving, that a greater share of the attention of the inventive and ingenious has been devoted to the perfection of W. than has been given to any other industry, and that now as it exists, the loom, with its manifold applications and accessories, is the most marvellous existing trophy of human genius. The essential mechanism and processes for W. a plain piece of cloth are simple; but the variety and complexity of the work which can now be mechanically performed by the loom are beyond all computation and statement. (See LOOM and JACQUARD LOOM.) In the practical operations of plain W., the web or warp is prepared by warping, which consists in laying the number of threads which run lengthwise in the chosen fabric in the same plane, and of equal length throughout. The warp yarn is wound off a number of bobbins equal to the number of threads it contains on a large revolving cylinder or drum, and from this the web of proper length is taken and wound around the beam of the loom, on which the threads are laid parallel, and as nearly as possible of the breadth of the woven cloth. The weft yarn is wound or filled in single threads on weaver's bobbins or pirns, which are placed in the shuttle. In the case of plain-woven fabrics a single shuttle only is needed, but in coloured or otherwise mixed fabrics the number of shuttles must correspond with the different colours and varieties of weft used. The W. of all figured and ornamental fabrics is a most complex and difficult art, and can only be attained by patient study and practice. See A. Barton's *History and Principles of W. by Hand and by Power* (Lond. 1878).

We'ber, Karl Maria Friedrich Ernst von, a German composer, was born at Eutin in the Duchy of Holstein, December 18, 1786. He sprang from a musical race, and his cousin, Konstanze Weber, was the wife of the great Mozart, whose music he loved most dearly. His father was of a restless, roving disposition, soldier, actor, and musician by turns, and his frequent changes of residence deprived W. when a child of a regular musical training. In 1796–97 the boy received lessons from Heuschkel the pianist at Hildburghausen, and afterwards from Michael Haydn at Salzburg. His next teacher, Kalcher at Munich, gave him a solid knowledge of counterpoint. In 1799 he composed an opera, *Die Macht der Liebe und des Weins*, and a large quantity of miscellaneous music. His next opera, *Das stumme Waldmädchen*, produced at Munich in 1800 when he was only thirteen years of age, was also performed in Vienna, Prague, and St. Petersburg. *Peter Schmoll und seine Nachbarn* was brought out at Augsburg in 1803 with indifferent success. After his musical education was completed at Vienna under the Abbé Vogler, he was appointed conductor of the opera at Breslau, where he gained experience in choral and orchestral writing. During the few years which followed he led a wandering but not

idle life, his principal works being a cantata, *Der Erste Ton*, and the operas of *Sylvana* and *Abu Hassan*. From 1813 to 1816 he was actively engaged in Prague as musical director of the opera, the most important of his compositions at this period being a cycle of stirring patriotic songs to Körner's words, *Leier und Schwert*, and a grand cantata *Kampf und Sieg* to commemorate the victory of Waterloo. W. was now a popular idol, and he left Prague to undertake the directorship of the newly-founded German opera at Dresden. In this city he carefully matured his three greatest operas. *Der Freischütz*, produced in Berlin in 1822, was the most brilliant popular and universal success in the history of German opera. It owed this to its original orchestral effects, its mystical character, its weird supernaturalness, and its fresh delicious melodies. Drawing his inspiration from the very essence of the German nature, his work found an echo in every German heart. His musical setting of the drama of *Preciosa* was warmly welcomed at Dresden in the same year. *Euryanthe* was brought out in Vienna in 1823 with indifferent success, but it now holds its place well in popular estimation, notwithstanding its absurd libretto. The favourite opera of its composer, it excels in ideality and imagination. In 1824 W. was commissioned by Mr. Charles Kemble to compose an opera on the subject of 'Oberon,' to a libretto by Planché. Already suffering from pulmonary disease, he came to London in the spring of 1826 for the production of this work, so full of luxurious softness and Eastern splendour. It was his last grand production. He died suddenly in Sir George Smart's house in Great Portland Street, June 5, 1826, and was buried in the Roman Catholic cemetery at Moorfields, whence his remains were transferred in 1844 to Dresden, where a statue (by Reichel) was erected to his memory in 1860. W. was practically the founder of a new school of opera, the Romantic, in which he is the most brilliant master. Beauty of form, harmonic invention, lovely flowing melody, are with him allied to a love of the legendary and the fantastic. He was of a sensitive and poetic temperament, and was original without waywardness or eccentricity. His orchestral colouring was masterly and effective, witness the Wolf's Glen scene in *Der Freischutz*. Among his miscellaneous compositions the Mass in E flat holds a high place. His works for the pianoforte are numerous, and the *Concertstuck*, the *Invitation à la Valse*, and many other delightful efforts, are sufficient of themselves to shed lustre on his name. The Jubilee Overture, together with the overtures to his three great operas, form a splendid group of orchestral masterpieces. See the Autobiography contained in his *Hinterlassene Schriften* (2 vols. 1828), J. Palgrave Simpson's *Karl Maria von W., the Life of an Artist, from the German of his Son* (Lond. 2 vols. 1865), and Jahn's *Karl Maria von W., ein Lebenskizze* (Leip. 1873).

Web'ster, Daniel, an American orator and politician, was born 18th January 1782, at Salisbury, New Hampshire. His father was a farmer who had risen to the rank of captain in the army during the Revolutionary War. He himself was during his boyhood engaged in agricultural work in summer, and only attended school in winter. At length, however, after a few months at Exeter Academy, he entered Dartmouth College in 1797, where he acquired a considerable mastery of ancient literature and the English classics, supporting himself meanwhile mainly by teaching. He graduated in 1801, then entered a lawyer's office, studied law for four years, and was admitted to the bar in 1805. He commenced practice in Boscawen, New Hampshire, but afterwards removed to Portsmouth. W. now began to take part in political life, warmly espousing the cause of the Federal party, but did not obtain a seat in Congress until 1812, when attention was attracted to him by a fine oration in opposition to the war policy of the Government. A speech on the Berlin and Milan decrees, delivered in June 1813, was his maiden effort in Congress, and he rapidly rose to a front rank among the members of his party. At the same time he assiduously cultivated his profession, making Boston his place of business, and becoming one of the most distinguished lawyers of the day. On the 22d December 1820—the bi-centenary of the landing of the Pilgrim Fathers—he delivered an oration at Plymouth which added greatly to his fame as an orator. In 1823 he finally established his reputation by a great speech on the Greek Revolution. In 1827 he was transferred from the House of Representatives to the Senate, where he sat until 1841. One of his most famous political speeches was delivered on the 26th and 27th January 1830, in reply to a South Carolina senator who had mooted for the first time the question of 'nullification,' or the right of a State to refuse obedience to the decisions of the central government. About this time the powerful Whig party began to be formed, its leaders being W. and Henry Clay (q. v.), two men of almost equal eminence. Perhaps it is to this fact, and to the divided allegiance of the party resulting from it, that the failure of either to attain the Presidency is to be attributed. From March 1841 to May 1843 W. held the office of Secretary of State, in which capacity he negotiated the famous Ashburton Treaty with England. He generously but unsuccessfully supported Clay's candidature for the presidency in 1844, and was himself disappointed of nomination in 1848. In the struggles as to the admission of Texas and California he adopted strongly the Northern or anti-slavery side, though his support of Clay's compromise measures in 1850 lost him his popularity with the Abolitionist party. He was again defeated in the presidential election of 1852, and died at Marshfield, Massachusetts, on the 24th October of the same year. Besides the speeches mentioned above, the following are among his most famous orations:—An address at the laying of the foundation of the Bunker Hill Monument, Boston, June 17th, 1825, and another on the completion of the monument in 1843: a panegyric upon Adams and Jefferson, who both died on the fiftieth anniversary of American Independence, delivered in Faneuil Hall, Boston, in 1826: and an address on the laying of the foundation of the Capitol extension at Washington, 4th July 1851. See *The Speeches, &c., of D. W.*, edited by Everett (Boston 1851); *Private Correspondence of D. W.*, edited by his son Fletcher (Boston 1857); Lanman's *Private Life of D. W.* (New York 1852; Lond. 1853); *Life and Memorials of D. W.* (New York 1853); Curtis's *Life of D. W.* (New York 1869); Marsh's *D. W. and his Contemporaries* (New York 1876); Smucker's *Life, Speeches, and Memorials of D. W.* (Phil. 1877); and Harvey's *Reminiscences of D. W.* (Bost. 1877).

Web'ster, John, an English dramatist, born in the latter part of the 16th c., wrote plays partly in conjunction with Dekker (q. v.). He lived on into the period of the Commonwealth, and died about 1654. His chief original dramas are *The White Devil, or Vittoria Corombona* (1612), and *The Duchess of Malfi* (1619). Both are full of tragic pathos and exquisite description, and secure for their author a high place among the selecter spirits of the Elizabethan age. Other productions of W. are *Guise, or the Massacre of France, The Devil's Law-Case, Appius and Virginia*. A collected edition of W.'s works, with a biography of the dramatist, was published by the Rev. Alexander Dyce (4 vols. 1830); and another by Hazlitt (4 vols. 1857-58).

Web'ster, Noah, an American lexicographer, was born at Hartford, Connecticut, 16th October 1758. He matriculated at Yale College in 1774, and graduated in 1778, his college career having been interrupted by a short campaign in the Revolutionary War under the command of his father, who was a militia captain. He was admitted to the bar in 1781, but instead of practising law opened a classical academy at Goshen, in the State of New York. Between 1783 and 1785 he published, in three parts, a *Grammatical Institute of the English Language*, which he afterwards made the basis of his famous *Spelling-Book*, of which 70,000,000 copies are stated to have been sold. His pamphlet, entitled *Sketches of American Policy*, published in 1785, was devoted to furthering the scheme for a United States Constitution; and when the Constitution was at last promulgated in 1787, he published an *Examination of its Leading Principles*. He was at this time principal of an academy in Philadelphia, but in the following year he went to New York and established an unsuccessful magazine known as *The American*. In 1789 he began to practise law at Hartford, and in this year were published his *Dissertations on the English Language*, a series of lectures which he had delivered in the Atlantic cities in 1786. After passing four years at Hartford, he returned to New York and started a daily newspaper, the *Minerva*, with a bi-weekly edition called the *Herald*, both of which still exist under the names of the *Commercial Advertiser* and *New York Spectator* respectively. The appearance of yellow fever in New York led him to publish in 1799 his *Brief History of Epidemics and Pestilential Diseases*. He had now settled at New Haven, and devoted himself almost

entirely to grammatical and philological labours. He published a *Compendious Dictionary of the English Language* in 1806, and a *Philosophical and Practical Grammar* in 1807; and shortly afterwards commenced his great work, the *American Dictionary of the English Language*. Finding his philological acquirements inadequate, he devoted himself for ten years to a study of etymology, forming a MS. *Synopsis of Words in Twenty Languages*. Seven more years were occupied in the actual compilation of the dictionary, his final researches being carried out in Paris and Cambridge, where he spent nearly a year in 1824-25. An edition of 2500 copies was published in America in 1858 (2 vols. 4to), and was followed in the next year by an English edition of 3000 copies. A second edition revised by himself was published in 1840-41, a third in 1847, a fourth in 1859, and a fifth, revised by Dr. Porter and containing 114,000 words, in 1864. W. published in 1833 an edition of the Old Testament, 'with amendments of the language,' and in 1839 a similar edition of the New Testament. In 1838 he revised *A History of the United States* which he had written in early life, and in 1843 published *A Collection of Papers on Political, Literary, and Moral Subjects*. He died at New Haven, 28th May 1843.

Wedge, in geometry, is a triangular prism, possessing therefore five sides, the two opposite sides of which are triangles connected by three rectangles. In mechanics the name is given to a similar shaped instrument which is effectual in splitting, cutting, or piercing. Axes, knives, pins, and needles are all of the nature of the W., the principle of which is identical with the principle of the inclined plane. The force which is applied to the *back* of the W. as it is being driven in has to overcome only the friction of the materials and the portion of the total pressure which is resolved perpendicular to the back. But as the total pressure is perpendicular to the faces, which are usually inclined at a large angle to the back, it is evident that this resolved portion is small.

Wedg'wood, Josiah, the founder of English pottery, was born at Burslem, Staffordshire, 12th July 1730. The descendant of a long line of potters, he entered his father's business, and, with the scantiest education, at once entered on his career as an inventor. He discovered new species of earthenware and porcelain, and such was the importance of these discoveries that in a few years they led to the export in place of the import of the finer earthenwares. In 1763 he obtained a patent for a fine cream-coloured porcelain, called 'Queen's Ware,' after Queen Charlotte, and his subsequent experiments added in all ten other different species of ware to the English manufacture, including the fine black 'basaltes' or 'Egyptian' and the famous 'jasper.' By attending carefully to design, and employing recognised artists, among them Flaxman, he raised to the level of a fine art what he had found little better than a barbarous expedient. At Chelsea he had a branch establishment for the painting and finishing of his wares, and in London a saleroom, which became a well-known resort of the fashionable. He received large orders from various parts of Europe, and one of his chief patrons was Catherine II. of Russia, for whom he executed a splendid 'landscape' service of many hundred pieces. In 1769 he removed his works some distance from Burslem, and the village which sprang up beside them he named Etruria. Here he reaped the magnificent fruits of his labours, and died January 3, 1795. W., beyond his own business, was a man of insight and ingenuity, well versed in several branches of natural philosophy. He invented a thermometer for measuring the higher degrees of heat required in the various arts, and the pyrometer, and adapted the engine-lathe to the uses of his art. The best period of his art is from 1779 to 1787, when the jasper ware—blue, with white figures in relief—attained its greatest beauty. The prices of W. ware have greatly increased; an Etruscan inkstand sold in Stafford for fourpence was bought in 1869 for £5, and copies of the Portland Vase have advanced from £40 to £180. W. was a Fellow of the Royal and Antiquarian Societies. Benevolent, pure-minded, ingenuous in private life, he took an active interest in public affairs, being chiefly instrumental in carrying out Brindley's Grand Trunk Canal, which unites the Trent, Severn, and Mersey. See Miss E. Meteyard's *Life of J. W., with an Introductory Sketch of the Art of Pottery* (2 vols. Lond. 1865-66), *A Group of Englishmen, being Records of the Younger Wedgwood[illegible] their Friends* (Lond. 1871), *W. and his Works* (Lond. 1[illegible]) and a *Handbook of W. Ware* (Lond. 1875); also a paper [illegible] Right Hon. W. E. Gladstone's *Gleanings* (Lond. 1879). For a description of W. Ware see article POTTERY.

Wed'more, a Somersetshire parish, lying on a southern slope of the Mendip Hills, 8 miles W.N.W. of Wells, has an interesting 14th c. church, with fragments of early sculptures resembling those of the nave of Wells cathedral. But older than its church is an underground chamber, discovered in 1878 in a field called the 'Court Garden' which, probably marking the site of Alfred's palace, carries us back to the Peace of W., concluded in 878 between Alfred (q. v.) and Guthrum of East Anglia. By this, 'the culminating event of Alfred's reign,' following as it did his defeat of the Danes at Ethandun, the Northmen agreed to evacuate Wessex and the part of Mercia S.W. of Watling Street, England being thus divided into *Engla-lagu* and *Dena-lagu*, while their king was baptized at Aller in the font restored last year to Aller church, and from *Guth-orm*, 'the fighting-dragon,' became Æthel-stán, 'the stone of excellence.' On 7th August 1878 the Millenary of the Peace was celebrated at W., and reference may be made to the reports of the Somersetshire Archæological Society for the speeches of Bishop Clifford and others on that occasion, as also to Professor Earle's *Peace of W., and how it touches the History of the English Language* (Oxf. 1878).

Wednes'bury (Old Eng. *Wodnesbeorh*), a manufacturing town of Staffordshire, 8 miles N.W. of Birmingham by rail, is an ancient place, since here in 914 Ethelfleda, Edward the Elder's sister, founded a castle. The present town, however, is almost wholly modern, the only old building being the church of St. Bartholomew crowning the former castle-hill. There are many new churches and chapels, and a free library and public baths were opened in 1878. W. owes its importance to its situation in the S. Staffordshire coal-field, whose yield in 1877 was 15,960,550 tons, and it is one of the great iron towns of the Black Country, manufacturing railway plant, gas tubes, gun-locks, &c. W. publishes three weekly newspapers, and with West Bromwich, Tipton, and Darlaston returns one member to Parliament. Pop. (1811) 5272 (1871) 25,030.

Wednes'day. See ODIN.

Wee'bo, or I'bo, one of the Querimba Islands, close to the coast of Mozambique, and about 170 miles N. of the town of that name. It belongs to Portugal, is fortified, and has some trade in ivory and gums, chiefly with Marseilles. The imports in 1875 were valued at £10,882, and the exports at £24,179. Pop. about 3000.

Weed, Thurlow, an American politician, born at Cairo in the state of New York, November 15, 1797, was first a cabin-boy on a Hudson river-boat, then a compositor, served as a volunteer in the war of 1812-15, established (1818) a newspaper, the *Agriculturist*, at Norwich in his native state, and was twice elected (1826-30) to the New York Assembly. In 1830 he settled at Albany, where he founded the *Evening Journal*; was one of the first members of the Whig party, and materially helped in the election of Governor Seward (1838 and 1840) and of Harrison to the Presidency (1840). His reputation as an adroit and successful wire-puller was now at its height, and he exercised a great influence in the distribution of 'the spoils of the victors,' but did not accept office. W. was an energetic supporter for the Presidency of Taylor (1848), of Scott (1852), of Seward (1856 and 1860), but gave a hearty adhesion to Lincoln when the latter was chosen, urged the vigorous prosecution of the war (1861-65), settled in New York (1865), and withdrew from editorial work (1868), though he still continued a vigilant guardian of the interests of his party, and was especially active during the constitutional crisis of 1876. He died in 1878. W. made some slight contributions to literature, but his autobiography and correspondence (not yet published) will unquestionably furnish invaluable material for the political history of the United States during the last fifty years.

Weeds are any plants which come up where they are not wanted, so that flower-garden plants among kitchen-garden crops, and carrots or turnips in flower-borders, are in this sense W. W. are mostly quick growers and very prolific, and in cases where they have had undisturbed possession they have crushed out native vegetation—*e.g.*, imported thistles in parts of S. America. The flora of highly-cultivated countries is gradually

being altered by agrestial W. introduced with cereal and other seeds from abroad.

Week (Goth. *vikô*; Low Lat. *septimana*; Gr. *hebdomas*; Heb. *shebua*, from *sheba*, 'seven'), with early Teutonic races, a period probably of the fourteen nights between a new and a full moon, since the Babylonian seven-days' cycle, introduced from Egypt to Rome in the 2d c. A.D., was not received by the heathen Franks till two centuries later. Under SABBATH the origin has been traced of this seven-days' week, which with the spread of Christianity supplanted the Greek *decades* and Latin *nundinæ*, and through Islam has found its way to Central Africa. Similarly the nomenclature of the seven days after the seven known planets reached Rome from Alexandria, and spread from Rome to the Roman and Teutonic races, the latter Germanising the Latin forms. Of Christian origin are the Gr. *kyriakē*, Lat. *dies dominica* (Fr. *Dimanche*), *Sabbath*, and *Lord's Day*, as also the Ger. *Sonnabend* and *Samstag* ('vigil of Sunday,' or the Sabbath); and, in German, *Mittwoch* has wholly superseded the older *Wodanstag* or 'Wodan's day.'

Weeks, Feast of. See PENTECOST.

Weep'ing Trees is a name given to certain trees having drooping secondary branches and remarkably long and pendulous branchlets, in consequence of which they possess a peculiarly graceful appearance, and form a pleasing contrast to trees of normal habit. For this reason and for shade W. T. are often planted as embellishments of gardens and pleasure-grounds, the custom not being confined to Western nations, but much in vogue also among the Chinese and their neighbours. The weeping willow is a general favourite, and in this species the habit is constant; but the weeping forms of British willows, ash, and elm are casual sports, and are propagated by grafts, &c. The weeping birch is not uncommon in a state of nature among the Scotch hills.

Weerdt, a town in Limburg, Holland, on the Südwillemsvaart Canal, 12 miles W.N.W. of Roermond. It has a fine church, containing the grave of Count Philip of Hoorn, a Franciscan monastery, and good schools, and carries on considerable brewing and tanning. Pop. (1874) 7073.

Wee'ver (*Trachinus*), the name given to certain species of *Teleostean* fishes, belonging to the family *Trachinidæ*, in which group the body is long, and may be either naked or scaly. The ventral fins are placed beneath the pectorals, and the palate bears teeth in the typical genus. The great W. (*T. draco*) and lesser W. (*T. vipera*) are the two familiar species occurring on British coasts. The former fish attains a length of from 10 to 16 inches. The colour is a reddish grey above, tinted with brown, the abdomen being of a lighter colour, and the gill-cover marked with yellow. The name 'W.' is a corruption of the French *La Vive*, given to the fish in allusion to the persistence of its vitality when removed from the water. The names Sea-cat and Sting-bull are applied to the great W., whilst the little W. is called Sting-fish and Otter-pike. The spines of the gill-cover and of the first dorsal fin are capable of inflicting sharp and painful wounds, which may exhibit inflammatory symptoms, due probably to some irritant secretion from the skin of the fish. The lesser W. attains a length of 5 or 6 inches; its colour is a reddish brown on the back and silver grey below. The lesser W. buries itself in the mud or sand, and also stings severely, bathers not unfrequently suffering from the effects of the wound.

Wee'vil, the name specially given to a family (*Curculionidæ*) of beetles or *Coleoptera*, the larvæ of which are highly destructive to grain and to various plants. The head is prolonged to form a snout or proboscis, used for boring, the antennæ being placed at about its middle. The mouth-parts are rudimentary, and are at the top of the snout. The family includes many species, a large proportion being very small. The larvæ are fleshy, footless grubs, and have large jaws; they enclose themselves in silky cocoons. Of the W. the best known have been described in special articles, such as Corn W., Pea W., &c. But mention may here be made of certain species belonging to less familiar genera than those just mentioned. The genus *Brenthus* or Oak W. bores, in its larval stage, into the white oak. The Seed W. are included in the genus *Apion*, and have black, pear-shaped bodies. *A. Sayi* lives in the pods of the wild indigo. *Rynchites* is another well-known genus, of which *R. bicolor* injures roses. The Nut W. belongs to the genus *Balaninus*. The snout is slender in the latter group, and is nearly as long as the body. The Pine W. belongs to the genus *Xylobius*, and *X. pales* is destructive to the pitch-pine especially. The White Pine W. is the *Pissodes strobi*, a species highly destructive to the tree from which it takes its name. The Plum W. (*Anthonomus prunicida*) is an American pest, whilst *A. quadrigibbus* infests the apple, and *A. suturalis* the cranberry. Another Plum W. is the *Conotrachelus nemephar*. The genus *Calandra* includes the famed *C. granorum* or Grain W., and the *C. palmarum*, which infests palms. Other species of W. are the *Sitophilus oryzæ* or Rice W., the Grape W. (*Cæliodes inæqualis*), and the Potato-stalk W. (*Baridius trinotatus*), the last of which infests the stalk of the potato-plant, and causes the death of the plant.

Weft is the name of the yarn or thread which is shot in a shuttle or otherwise across the warp or web in Weaving (q. v.).

Weight of a given body is the force with which that body is attracted to the earth, and is, in accordance with Newton's Second Law, measured by the product of the mass into the acceleration. For all bodies at the same distance from the earth's centre the acceleration is the same; and hence the W. is simply proportional to the mass. Consequently we may compare masses by comparing their weights; and this is really what is done in all operations of *weighing*. Thus, if two masses are suspended at the extremities of an equal-armed lever, the lever is in equilibrium; hence the weights acting at the extremities, and therefore the masses, must be equal. This is the principle of the ordinary Balance (q. v.). The W. of a mass may also be estimated by means of a spring-balance. See SPRING. See also GRAVITY.

Weights and Measures. Under this heading it is usual to consider the various standards of mass and length which are or have been used amongst civilised communities. To compare any two quantities of the same kind, it is necessary to express them in terms of a common unit (see UNIT), and upon the choice and definition of this unit the character and accuracy of our comparisons must depend. Originally, no doubt, the standards of length were taken from the different parts of the human body, as the names foot, digit, palm, span, cubit, ell, &c., imply, and as we may safely infer from the word grain, the standards of mass were chosen from some common convenient and tolerably definite source, such as afforded by grains of barley or other cereal. As the intercourse between nation and nation increased and commerce arose it became necessary to fix more definitely the standards of reference, and not the least service rendered to civilisation by the Romans was the construction of a universal system of W. and M. which all their subjects were forced to use. At the decline of the Roman empire, however, the imperial standards were lost, and each community, retaining the old names, formed its own local standards. And in this we find the explanation of the existence throughout Europe of such words as mile, pound, ounce, applied to similar though quantitatively different standards of length and mass. This multiplicity of standards became confusing and inconvenient as the small independencies of the dark and middle ages merged into the Great Powers which now rule the continent of Europe; and simultaneously the rapid rise of commerce required a readjustment in the way of simplification of these standards. Henceforth the fixing of legitimate W. and M. became a subject of Government legislation, and, with the increased demand for accuracy, a scientific problem of no small difficulty. As in all practical applications of pure science, France led the way, and in 1795 established the Metric System (q. v.) of W. and M. as the only authorised system throughout her dominions. The fundamental standard of this system, the mètre, though originally derived from Delambre and Méchain's measurement of the size of the earth as a ten-millionth part of a quadrantal arc from pole to equator, is practically defined as the distance between the ends of a rod of platinum at 0° C. Similarly are all the national standards of length defined, including our own Yard (q. v.). The units of mass, such as the British Pound (q. v.)[illegible]he French kilogramme (see METRIC SYSTEM), are in[illegible]anner fixed by material standards, generally a mass of pl[illegible] preserved in the Government offices. Copies

are made of these definite standards, so that should the standards by any accident be destroyed or damaged it shall be a comparatively easy matter to restore them. All other measures, whether of mass, length, or capacity, can be and are now defined in terms of the fundamental standards of mass and length; but for these we refer to special articles, such as AVOIRDUPOIS WEIGHT, FOOT, GALLON, GRAIN, GRAMME, INCH, OUNCE, TROY WEIGHT, &c., besides those already indicated. In connection with the W. and M. Act of 1878, an Order of Council (February 4, 1879) has been issued, establishing the *Cental* of 100 lbs. avoirdupois as the new standard hundredweight.

Law Regarding W. and M.—Various recent statutes have been passed with a view to establish uniformity in the W. and M. of the United Kingdom. The most recent is the 41 and 42 Vict. (1878), which came into force January 1, 1879. By these statutes an imperial standard yard, pound, gallon, and bushel is fixed. All local measures of capacity are abolished. The imperial standard gallon is 277·274 cubic inches. The legal stone is fixed at 14 pounds avoirdupois. All articles sold by weight must be sold by avoirdupois, except gold, silver, platina, and precious stones, which are still to be sold by troy weight. Any one who uses or has in his possession for use for trade a weight or measure which is not of the denomination of some Board of Trade standard, shall be liable to a fine not exceeding £5.

Weil, Gustav, a celebrated living Orientalist, born of Jewish parents at Sulzburg in Baden, April 24, 1808, studied at Heidelberg (1828–30), at Paris, and at Cairo, where he resided for five years. In 1838 he became librarian at Heidelberg University, in 1845 extraordinary Professor, and in 1861 ordinary Professor of Oriental Languages. His works are *Goldene Halsbänder* (Stutt. 1836), a translation from Zamachschari; *Die Poetische Literatur der Araber* (Stutt. (1837); *Tausend und eine Nacht* (4 vols. Stuttg. 1837–41), the best German translation of the famous tales; *Einleitung in den Koran* (Bielef. 1844; 2d ed. 1878); *Mohammed, der Prophet* (Stuttg. 1843); *Geschichte der Khalifen* (Mannh. and Stuttg. 3 vols. 1846–51), with its continuation, *Geschichte des Abbassidenkhalifats in Ægypten* (Mannh. and Stuttg. 2 vols. 1860–62); his translation, *Leben Mohammeds nach Mohammed Ibn Ishak, bearbeitet von Abd-el-Malik Ibn Hisham* (Mannh. and Stuttg. 2 vols. 1864); and his *Geschichte der Islamischen Völker von Mohammed bis zur Zeit des Sultans Selim* (Mannh. and Stuttg. 1866), the result of thirty years' historical study.

Wei'mar, capital of the Grand Duchy of Saxe-Weimar-Eisenach, on the left bank of the Ilm, about 110 miles W.S.W. of Leipzig. The grand-ducal palace, rebuilt under Goethe's direction 1790–1803, contains many curiosities and works of art commemorative of the four great poets who have given W. its celebrity—Goethe, Schiller, Herder, and Wieland, besides the original cartoons of Leonardo da Vinci's 'Last Supper,' and several pictures by Scheffer and other modern artists. Other places of interest are the Rothe Schloss, built in 1574, where the chamber holds its sittings; the so-called Französische Schlösschen, containing the grand-ducal library, with its 150,000 volumes, 8000 maps, and 500 old works on genealogy, &c., besides pictures and busts of Goethe, Schiller, and others, and relics of Luther, Gustavus Adolphus, &c.; the Fürstenhaus, at one time the residence of the Grand Duke Karl August, the munificent patron of the poets, now the central telegraph office; the Stadt-Kirche, erected about 1400, containing Cranach's 'Crucifixion' and the monuments of Herder and Duke Bernhard; the museum (1869); the theatre, so celebrated under the management of Goethe and Schiller; statues of the four poets and of Duke Karl August, &c. The houses in which the poets lived still stand, but their interest is of course literary, not architectural. Besides the Stadt-Kirche already mentioned, there are various churches of different persuasions in W., a large number of schools, charitable institutions, banks, &c. There are hardly any manufactures. Across the beautiful park to the S.E. lies the village of Ober-Weimar. Pop. (1877) 19,267. W. has never distinguished itself in political history except by the meeting of deputies in 1862 to discuss the unification of Germany. See Schöll's *W., Merkwürdigkeiten einst und jetzt* (Weim. 1857), Springer's *W., Classische Stätten*, (Berl. 1867), and the descriptions of 'Pumpernickel' scattered through Thackeray's Works.

Weingunga (*Waingunga*), a considerable river of Central India, which flows after a S. course of 350 miles into the Wurdha, then called the Pranheta, a tributary of the Godavery. It is navigable for some distance during the rains.

Weir, or **Wear**, a dam or dyke thrown across a river or stream to raise the level of the water for the purpose of diverting it to drive machinery, irrigate land, or supply towns, or to render the upper portion of the stream navigable, or for some other purpose. A W. is constructed of stone, or, as in America, of timber, crossing the river at right angles or obliquely. Sometimes it takes the form of a V, the apex pointing up the river. The up-stream face is vertical or nearly so, and the down-stream face slopes gently or is cut into a series of steps which break the overflowing water into a number of diminutive cascades. Great engineering skill is required for the construction of a W. The term W. is also applied to an escape-pipe for carrying off surplus water from a reservoir.

Weiss'enfels, a town of Prussia, province of Sachsen, on the Saale, 12 miles S. of Merseburg by rail. It is surrounded by walls, outside of which are the ruins of an old castle of the Dukes of W., now used as a barrack. W. has two churches, a teacher's training-school, and a deaf and dumb institution, manufactures of sugar, machinery, porcelain, leather, jewellery, and bijouterie, much of which goes to the Leipzig fair, and (in the neighbourhood) sandstone quarries. Pop. (1877) 17,904. See Sturm's *Chronik der Stadt W.* (W. 1846).

Welch, John, D.D., a Scottish divine, son of the proprietor of Collieston in Nithsdale, was born about 1570, spent part of his youth in the society of Border thieves, and 'lived for a time entirely by plunder,' but growing ashamed of his wickedness, was reconciled to his family and studied for the church. Ordained minister at Selkirk before he had reached his twentieth year, he was successively called to Kirkcudbright and Ayr, where he proved himself a bold and successful preacher of the gospel. His opposition to James VI.'s arbitrary policy led to his imprisonment (1605), and banishment (1606) from the kingdom. He sought refuge in France, and became pastor of a Protestant congregation first at Nerac, and afterwards, for sixteen years, at St. Jean d'Angely, in Lower Charente. Owing to declining health, he obtained permission to return to England, and died in London 1623. His wife, Elizabeth Knox, third daughter of the great reformer, died at Ayr in January 1625.

Welck'er, Friedrich Gottlieb, classical archæologist, was born at Grünberg, November 4, 1784, studied at Giessen, and visited Rome in 1806, where he became acquainted with Zoega. In 1809 he was appointed extraordinary Professor of Archæology at Giessen, in 1816 Professor of Philology at Göttingen, and in 1819 at the newly-founded University of Bonn. In 1826 and again in 1832 his political writings brought him under suspicion, and he was tried for sedition, but was on both occasions acquitted. He died December 17, 1868. To W.'s rare union of æsthetic feeling with profound and exact learning, philology owes much. His chief works are *Die Aeschyleische Trilogie* (Darmst. 1824); followed by the supplement occasioned by G. Hermann's attack upon his theory, *Nachtrag nebst einer Abhandlung über das Satyrspiel* (Frankf. 1826); *Die griech. Tragödien mit Rücksicht auf den epischen Cyklus* (3 vols. Bonn, 1839); *Der epische Cyklus, oder die Homerischen Dichter* (2 vols. Bonn, 1835–49); *Griech. Götterlehre* (3 vols. Gött. 1857–62); *Alte Denkmäler* (5 vols. Gött. 1849–64); and *Kleine Schriften* (5 vols. Bonn, 1844–67).—**Karl Theodor W.**, brother of the preceding, was born at Oberofleiden, in Ober-Hessen, March 29, 1790, studied at Giessen and Heidelberg (1807–11), and became in 1814 Professor at Keil, in 1816 at Heidelberg, in 1819 at Bonn, and in 1823 at Freiburg. In 1831 he entered the Baden Chamber, where he soon became leader of the Liberals. In 1833 he was suspended, was restored in 1840, again suspended in 1841, became in 1848 representative of Baden at the German National Assembly, from which he withdrew in June 1849, and next year entered the Baden Chamber. He died at Heidelberg, March 10, 1869. W. edited with Rotteck the *Staatslexikon* (12 vols. Altona, 1834; 3d ed. Leip. 1856–66).

Weld, Would, or **Woold**, is *Reseda Luteola*, a glabrous annual or biennial plant of from 2 to 3 feet high, a native of Europe, N. Africa, and W. Asia, and frequent on waste ground

through the British Isles, showing a preference for calcareous soil. It also bears the name of Dyer's Weed or Rocket, and Yellow Weed, from its being used by dyers to dye woollen stuffs yellow, and from the linear-lanceolate undivided leaves resembling those of the genuine rocket. W. is not now so extensively employed for dyeing purposes as formerly. The pigment pervading the whole plant has been named 'Luteolin.' To obtain it in its fulness the W. must be cut before the fruit commences to develop, and to extract the whole yield boiling for nearly an hour is necessary. A paint is also made from it called 'Dutch-pink.'

Weld'ing, the process of uniting two or more pieces of a fusible material by heat and hammering or pressure. Few metals except iron have the property of being welded. Horn, tortoise-shell, and some other substances, may likewise be completely united by heat.

Welhaven, Johan Sebastian Cammermejer, a Norwegian poet, born 22d December 1807 at Bergen, studied at Christiania from 1825, where he became 'Lector' in 1840, and 1846 Professor of Philosophy. His first appearance in literature was closely connected with the political and literary ferment which about 1830 produced a new epoch in the social history of Norway (see NORWAY, *Language and Literature*). The views of W. were fullest expressed in the poem *Norges Dæmring* (Christ. 1834), which with the boldest freedom lashed the weaknesses of the Ultra-Norse School that strove to curb the powerful influence of Danish culture. Before this he had written *Fire Dusin Complimenter tie Henrik Wergeland* (Throndhjem 1838) and *Henrik Wergeland's digtekunst og Character* (Christ. 1839), but henceforth from the long and bitter controversy he had now called forth W. in the main held aloof. The chief events of the remainder of his life were the issues of four collections of poems at Christiania in 1839, 1845, 1848, and 1860, marked by great finish of form and beauty of style, and of his *Reisebilleder og digte* (Christ. 1851). Of great merit are his romances *Asgaardereien* and *Eyvind Bolt*, and the short sketches *Holberg* (Christ. 1854) and *Ewald og de Norske Digtere* (*ib.* 1863). W.'s *Samlede Skrifter* are in 8 vols. (Copenh. 1868). He died 21st October 1873.

Welles'ley, Richard Colley, Marquis, an English statesman, and one of the greatest of the governors of India, was the eldest son of the Earl of Mornington, and was born in Dublin, 20th June 1760, nine years before his yet more illustrious brother, the first Duke of Wellington. He was educated at Eton and Christ Church, Oxford, and always retained a rare skill in the composition of Latin verse. After filling some minor offices at home, he was selected as Governor-General of India in 1797, and filled that post for nearly eight years. It was Lord W.'s policy that determined the supremacy of the English throughout India, in contradiction to the views of his two immediate predecessors, and by no means in accordance with the expressed instructions of the Court of Directors in England. During his rule Tippoo Sultan was overthrown and killed at the siege of Seringapatam; the Mahratta power was crushed by the victories of Sir Arthur Wellesley at Assaye and Argaum, and of Lord Lake at Laswaree. The Mogul Emperor was restored to his throne, but became a pensioner of the English government; the Nizam of Hyderabad was diverted from his French alliance, and guarded with a contingent officered by Englishmen. The greater part both of the Madras Presidency and of the N.W. Provinces became English territory, and the political map of India remained almost as he had left it for the next forty years. The principles of his policy have been described as 'the subsidiary system,' in accordance with which every native chief who had yet sufficient power to be formidable was compelled by diplomacy or force to accept an English alliance, guaranteeing to him internal sovereignty, but generally enforcing a cession of territory in order to support a British force. The leading subordinate agents of his policy were men like Malcolm (q. v.), Elphinstone (q. v.), Metcalfe (q. v.), and Munro (q. v.). All his public conduct was on an equally grand scale. He built the present magnificent Government House at Calcutta in 1804, founded the College of Fort William, for the education of civilians and the promotion of Oriental learning, and always opposed himself to the trading monopoly of the Company. It is to the credit of the Court of Directors, who were continually at variance with him on both political and financial questions, that they voted to him on his retirement a pension of £5000, and afterwards a further sum of £20,000, and erected his statue in the India House. He returned to England in 1805, was for a short time (1809) Foreign Secretary, and twice (1821-28 and 1833-34) Lord-Lieutenant of Ireland, where his policy was conciliation. He died at Kingston House, Knightsbridge, 25th September 1842, and lies buried in Eton College Chapel. He had been created Marquis in 1799, but left no sons, and his early title of Earl of Mornington has since been absorbed in that of Duke of Wellington. See a Life by Pearce (3 vols. Lond. 1845); Montgomery Martin, *Despatches, Minutes, and Correspondence of the Marquis of W. during his Administration in India*, and *Mission to Spain* (6 vols. Lond. 1836-88); and Sidney J. Owen, *Selection from the Despatches, Treaties, and other Papers of the Marquis W.* (Oxf. Clar. Press, 1877).

Well'ingborough, a town of Northamptonshire, England, on the Nene, 9 miles N.E. of Northampton by rail. It has a large elegant parish church (restored 1861-74), two other episcopal churches, a town-hall (1821) and corn exchange (1861). Medicinal wells in the neighbourhood give name to the town. Shoemaking is the principal industry, but iron-mining is being rapidly developed, and there is some trade in corn. Pop. (1871) 9385.

Well'ington, a town of Shropshire, England, on the Shrewsbury and Shropshire Canal, 10 miles E. of Shrewsbury by rail. It has 6 churches and chapels and a handsome town-hall and assembly-rooms. The surrounding district is rich in coal and iron, and has numerous mines and limestone quarries. The town is actively engaged in the nail trade and other industries. Pop. (1871) 5926.

Well'ington, a town of Somersetshire, England, 8 miles S.W. of Taunton by rail. It has a beautiful Gothic church and 8 chapels. Woollen goods are manufactured. Pop. (1871) 5119. The place dates from the time of Alfred the Great, and appears in Doomsday Book as Walintone. The Duke of Wellington takes his title from this town.

Well'ington, the capital of New Zealand, is situated near the southern extremity of the North Island, at the head of Port Nicholson, an inlet measuring six miles by five, and forming a magnificent natural harbour. W. was the first settlement of the New Zealand Land Co., and was founded on 22d January 1840. In 1865, on account of its central position, it was made the capital of the colony in the place of Auckland. The town is built on a strip of flat land at the base of steep hills, and is lighted with gas, well supplied with water, fairly paved, and traversed by a line of tramway. In consequence of the frequent occurrence of earthquakes, the houses and public buildings are nearly all of wood. Among the latter the principal are the governor's residence, the Houses of Parliament, colonial museum, an Anglican and a Roman Catholic cathedral (the latter redecorated in 1878). The climate is healthy but boisterous. W. has an extensive commerce, iron foundries, and a patent slip capable of accommodating vessels of 2000 tons. Pop. (at the census of 1878) 19,126.

Well'ington, Arthur Wellesley, Duke of, was born May 1, 1769, or more probably a day or two earlier, at Dangan Castle, County Meath, Ireland, or possibly at Mornington House, Dublin, both the date and the place being subjects of controversy. He was the third son of Garrett Wesley, first Earl of Mornington, and the younger brother of the Marquis of Wellesley (q. v.). The family was descended from two English stocks, the Wesleys of Sussex, and the Cowleys, Coolleys, or Colleys of Rutlandshire, both of which had been settled in Ireland for at least two centuries. W.'s earliest education was received at a private school in England. At the age of twelve he lost his father; and his mother, a woman of strong and even harsh character, who is said to have considered him hopelessly stupid and unfit for any but the most commonplace career, sent him, after a short time at Eton, to the military college of Angers in France, where he studied under the celebrated engineer Pignerol, and completed his education. On the 7th March 1787 he was gazetted ensign in the 73d regiment, and his military career began. In less than a year he became lieutenant in the 76th regiment, was for some time in the 41st, exchanged from the line into the 12th Light Dragoons, and got

his company in the 58th regiment on the 30th June 1791. After passing through the 18th Light Dragoons, he obtained his majority in the 33d regiment, of which he became lieutenant-colonel by purchase in 1793. He had been returned to the Irish House of Commons in 1790 by his family borough of Trim, and in the course of his duties as aide-de-camp to the Marquis of Camden, then Lord-Lieutenant of Ireland, he met and became attached to Catherine Pakenham, third daughter of the Earl of Longford. Their marriage was at that time prevented by family opposition, and it was not until fifteen years later (April 1806) that it was accomplished. He first saw foreign service in 1794, when he took part with his regiment in the Duke of York's disastrous campaign in the Low Countries, where he acquitted himself with credit, but without striking distinction. Thoroughly disgusted, as he had every reason to be, with his first experience in the field, he attempted next year to quit the army and obtain employment in the Irish government service. In this attempt, fortunately for England and Europe, he did not succeed. His regiment formed part of a military contingent destined to co-operate with Admiral Christian in the West Indies in 1795, but the expedition was driven back by storms, and the destination of the regiment was shortly afterwards changed to India. Prevented by ill-health from leaving England with the 33d, W. rejoined it at the Cape, and landed in India in February 1797. The final struggle against the French power was still in progress, and W. was almost as largely instrumental in crushing it in the East as he afterwards was in the West. Under the command of General Harris he turned the right wing of Tippoo Sultan at Malaveli, and thus decided the victory (27th March 1799); he commanded the reserve at the storming of Seringapatam by Baird (4th May 1799); and in the following year he conducted a brilliant expedition against the robber horde of a chief named Dhoondiah Waugh, which was completely successful. The influence of his brother, who was then Governor-General of India, aided him to come to the front, and on the outbreak of the Mahratta War in 1803 he was appointed to a chief command. After reducing the fort of Ahmednuggur, he attacked Scindia's army at Assaye. He had only 1500 British and 7000 native troops, with 17 or 18 guns, while his adversary commanded an army of 50,000 men, with 128 guns. The result was one of the most brilliant of all his victories, and may be said to have been largely due to his personal courage and resolution. The victory of Argaum (q. v.) and the capture of Gawulghur finally crushed the Mahratta power. W. was made Major-General and K.C.B., and returned to England in 1805 with an established military reputation. Entering the House of Commons in the following year, he became in 1807 Chief Secretary for Ireland under the Duke of Richmond, and in the same year he served with distinction under Lord Cathcart in the expedition to Denmark, which ended in the bombardment and capture of Copenhagen.

The most stirring and glorious period of his life was now about to commence—the seven years between 1808 and 1815, in which he vanquished the most famous of Napoleon's generals and finally Napoleon himself, received thirteen times the public thanks of Parliament, and rose through all the grades of the peerage until he became Duke of W., Prince of Waterloo, Duke of Ciudad Rodrigo and Vittoria, Grandee of Spain, Marquis of Torres Vedras, Count of Vimiera, Knight of the Garter and of the Golden Fleece, and Field-Marshal in the armies of England, Russia, Austria, and Prussia. On the 12th July 1808 he sailed from Cork at the head of 12,000 men, and landing at the mouth of the Mondego in Portugal on the 9th August, commenced his march towards Lisbon, which was held by the French under Junot. He defeated the enemy in the skirmishes of Ovios and Roliça and in the great battle of Vimiera, and would probably have taken Lisbon but for the pusillanimity of Sir Harry Burrard, who had been sent out by the Government to supersede him, and who was in turn superseded by Sir Hew Dalrymple. As it was, the extremely unpopular Convention of Cintra was the only result of the campaign. Next year, however, found him commander-in-chief of the troops in the Peninsula, and opposed to Soult and Victor, who held the town of Oporto and the northern province of Portugal. On 12th May 1809, by one of his most brilliant and daring manœuvres, he crossed the broad and rapid Douro in the face of Soult's army and compelled the evacuation of Oporto. On the 27th and 28th July he defeated Victor in the sanguinary battle of Talavera, but was forced to abandon the fruits of his victory owing to the inactivity of the Spanish army under Cuesta. In the campaign of the following year the brilliant Masséna was his opponent. Securing Almeida and Ciudad Rodrigo as bases of operation, the French general compelled W. to retire into Portugal. The victory of Busaco secured for the British their retreat to the strongly-fortified lines of Torres Vedras, before which Masséna soon found himself in a hopeless position. It was equally impossible to force the lines and to maintain his army in the devastated country, so that he in turn had to retreat. W. followed him closely, repulsed an attack at Fuentes de Onoro, and took Almeida (May 1811). Repulsed at Badajos in June, W. turned his attention to Ciudad Rodrigo, which he took after a sanguinary struggle (19th January 1812). He then returned to Badajos, and stormed it also in spite of the most determined resistance (7th April). The French had now lost all hold upon Portugal. Masséna had been superseded by Marmont, who wisely attempted to concentrate the forces which had hitherto been scattered over the wide extent of the half-subjugated country. Salamanca was the point which he determined to hold at all costs. The two armies faced each other, and occupied themselves with manœuvres and counter-manœuvres for more than a month, until at last, on the 22d of July 1812, the decisive blow was struck. Marmont's force amounted to 42,000 men with 74 guns, W.'s to 43,000 English and 3500 Spaniards with 60 guns. The battle was short and fierce, and resulted in the total rout of the French, who lost 6000 men, 2 eagles, and 6 standards. W. now marched upon and took Madrid, and was preparing to advance still further when the stubborn resistance of Burgos checked him, and forced him to retire from Madrid and take up his winter-quarters in the lines of Agueda. He had all along had to contend with insufficiency of supplies and clothing, lukewarmness on the part of the native population, and insubordination among both officers and men, and never were these troubles more aggravated than at this crisis; while a factious opposition at home was attacking his policy and depreciating his triumphs. On the other hand, the disasters of Napoleon in Russia confirmed his hopes of being able to bring the war to a successful close by the expulsion of the French from the Peninsula, and he entered upon the campaign of 1813 with firmness and confidence. Nor was his confidence belied. He completely routed Jourdan and Joseph Bonaparte at Vittoria on the 21st June 1813, taking 151 guns and all the enemy's ammunition, a victory which gained him the rank of Field-Marshal. Pamplona and San Sebastian fell in the course of the autumn, the latter after a determined resistance; and the French, now under Soult's command, after suffering another reverse on the Nivelle (November 10), were fairly driven through the Pyrenees, and the war was carried into their own country. The floods to which the south of France is so subject impeded military operations in the early part of 1814, but on the 10th of April the two armies again faced each other at Toulouse. Napoleon had in fact abdicated and the war was at an end, but intelligence of the event had not reached the generals. The battle was one of the bloodiest of the whole war, and resulted in the precipitate retreat of the French, who nevertheless have more than once claimed it as a victory. On learning of the close of the war W. hastened to Paris, and in the early summer returned to England. It was now that he received his dukedom, but he was not yet permitted to rest upon his laurels. In August he again left for Paris as British Ambassador, and in January 1815 he replaced Lord Castlereagh at the Congress of Vienna. The escape of Napoleon from Elba (March 1815) put a sudden close to the Congress, and W. gave up his diplomatic to resume his military functions. By common consent he was named commander-in-chief of the allied armies in the Low Countries, and assumed the command in Brussels on the 15th of April 1815. Two months later (18th June) was fought the great Battle of Waterloo, the last and crowning triumph of his military career. On June 21 he crossed the French frontier, and on July 3 invested Paris.

During the armed occupation of France W. made Paris his headquarters, and contributed greatly by his firm and judicious policy to the successful re-establishment of the monarchy, moderating at the same time in favour of conquered France the vindictive passions of his conquering allies. To this period belongs one of the gravest charges ever brought against him

—the accusation of lack of generosity in his conduct towards Ney (q. v.)—but to this attempt at detraction no weight is to be attached. Two unsuccessful attempts were made to assassinate him during his residence in Paris, one of them by a man named Cantillon, to whom Napoleon afterwards left a legacy. In 1818 he returned to England, where his wealth had meanwhile increased as largely as his honours. The nation proved its gratitude by more solid proofs than titles. After Talavera he had received a pension of £2000 a year; after the taking of Ciudad Rodrigo another £2000 a year was added; after Salamanca, a sum of £100,000 was voted for the purchase of lands to be held by him. On the close of the Peninsular campaign he received a grant of £400,000; after Waterloo another £200,000. His share of the Waterloo prize-money amounted to £60,000, half of which he gave up to the fund for the widows and orphans. The estate of Strathfieldsaye, in Hampshire, was purchased for him at a cost of £230,000, and Apsley House, in Piccadilly, was built for him at the expense of the nation.

During the early years of the peace he took little part in public affairs. In 1822 he represented England at the Congress on Spanish Affairs held at Verona, and in 1826 he went on a special mission to St. Petersburg. As Master-General of the Ordnance he held a seat in the Cabinet, and frequently took part in debates in the House of Lords, but did not come forward prominently as a politician until in 1827 Canning became prime-minister. He then resigned his seat in the Cabinet and the post of Commander-in-Chief of the Army, in which he had succeeded the Duke of York a few months previously. Being accused in the House of Lords of caballing to obtain the premiership for himself, he proclaimed himself quite unfitted for it and unambitious of it. Yet only eight months afterwards he was called upon by the King to form a ministry, and consented. The sagacity which must be regarded as his leading quality as a statesman, proved to him the impossibility of stemming the tide of the age, and he compromised his severe Tory principles and saved his party for the time by the repeal of the Test and Corporation Acts, and the passing of the Catholic Emancipation Bill—a change of politics which led him into a duel with the Earl of Winchelsea. Though he had thus given way upon the Catholic question, the agitation for Reform was more than he could stomach. After declaring in explicit terms his belief in the perfection of the then existing system of representation, he resigned office (November 22, 1830), and did not resume it until 1834, when he held the whole government in his hands until the return of Sir Robert Peel from Italy, and then took office as Foreign Secretary. His unpopularity during the Reform-Bill struggle was intense—so much so that the windows of Apsley House were broken by the mob, who also hooted him in the streets. It was not until he again compromised his life-long prejudices by promoting the passage of the Corn-laws that he fully regained his hold upon the popular affections. He again became Commander-in-Chief of the Army in 1842, and held the post until his death. Towards the close of his life he retired once more from any active participation in public affairs, though he still attended the House of Lords, and even took part in the debates, his manner of speaking being plain and unstudied, but, it is said, highly effective from its force and earnestness. He was the intimate private friend and confidential adviser of the present Queen, whom he accompanied on a visit to Belgium and the field of Waterloo in 1850. During the latter years of his life his middle-sized but strongly-knit figure, aquiline face, and white hair, were to be seen every day in Piccadilly or Hyde Park, where he took exercise, generally on horseback, with great regularity. In August 1852 he went down to Walmer Castle, where he was entertaining a party of guests. On the 13th of September he was apparently in his usual health, but on the morning of the 14th he was seized with an apoplectic fit, and died on the same evening. After lying in state for five days at Chelsea Hospital, he was buried in St. Paul's Cathedral. The character of W.'s genius is not difficult to apprehend. There was nothing tortuous, astute, or deceptive about it. His courage was immense. No general ever grasped the difficulties of a situation more clearly; his eagle-glance rapidly and thoroughly took in all possible perils and mishaps, yet his sagacity never daunted his resolution. His most momentous military movements were undertaken with a boldness of heart and hope that inspired his officers and troops with unbounded confidence in his success. In the art of strategy he was unsurpassed; he never flattered his troops, but Napoleon himself had less power than the plain Englishman in calling forth heroic valour in every form. England never had before, and may never have again, so illustrious a commander. Of the science of politics he was not a student, but even here the simple greatness of his character displayed itself. He was never a paltry partisan, and he would never stoop to carry on an ignoble and factious strife when the conflict had really closed. Save Nelson's, no name amongst the names of modern warriors is more sacredly shrined in the hearts of Englishmen than that of W.

The lives of W. are very numerous, the principal being those of Wright (Lond. 1839-41), Maxwell (Lond. 1839-41; 6th ed. 1862), Stocqueler (Lond. 1852), Wilson (Lond. 1853-54), Williams and Gaspey (Lond. 1853-56), Ward (Lond. 1852), Maurel (Brussels 1853), Macfarlane (Lond. 1853), Lord F. L. Gower, afterwards Earl of Ellesmere (Lond. 1852), Brialmont (Par. 1856-57; trans. by Gleig, Lond. 1858; condensed, Lond. 1862; popular ed. revised 1875), Yonge (Lond. 1860). The great storehouse of information on his military career is his *Despatches*, edited by Colonel Gurwood (13 vols. Lond. 1834-39; 2d series, 12 vols. Lond. 1844-65), as well as the *Supplementary Despatches, Correspondence, and Memoranda*, edited by his son, the present Duke of W. (of which the 7th vol. appeared in 1878). See also Lamartine's *W. and Waterloo* (Lond. 1852), Lemoinne's *W. from a French Point of View* (Lond. 1852), Timbs' *Wellingtoniana* (Lond. 1853), Lendy's *Campaigns of Napoleon and W. in 1812, 1813, and 1814* (Lond. 1861), Hamley's *W.'s Career* (Edin. 1860), Büdinger's *W., Ein Versuch* (Leip. 1869). On the general history of his career, see Napier's *Peninsular War*, Alison's *History of Europe*, Thiers' *History of the Consulate and Empire*, Sir Robert Peel's *Memoirs*, and the political memoirs of the Catholic Emancipation, Reform, and Corn-Law struggles.

Wellingto'nia represents one of the giants in vegetable life, and is a name given by Professor Lindley to a conifer, native of California, but afterwards it was known to botanists that the tree ranged under the genus *Sequoia*, another species of the genus having been described some years earlier under the name of *S. sempervirens*. The cognomen of W. is 'big tree of California,' and the tree exists over a district of about 200 miles, at an elevation of 4500 to 6500 feet above sea-level in that country. The loftiest specimens attain to a height of 325 feet, with a maximum diameter of 61 feet. They thus surpass in bulk of timber every existing tree, although several species of *Eucalyptus* exceed them in height. The tree is now familiar through being grown as an ornamental plant in gardens and parks in Europe, and has also been introduced into Australia.

Wells, a city of Somersetshire, England, 6 miles N.N.E. of Glastonbury by rail, lies circled by the Mendip Hills, and takes its name from St. Andrew's ancient well. The matchless cruciform cathedral (restored 1842-74) is 371 feet long by 135 across the transepts, and, built between 1206 and 1465, is mainly in the Early English style. Its noblest features are the central (160 feet) and two western towers (130 feet) and—Freeman notwithstanding—the western front, adorned by 153 life-size statues of saints and kings and over 400 smaller figures. The baronial Bishop's Palace, with Jocelyn's 'stately chapel' (1236), the Vicar's Close (1363), the beautiful Deanery (1472), and St. Cuthbert's Church, are among the historic monuments of W.; its later buildings include St. Thomas' (1859), a town-hall (1780), and the county lunatic asylum (1848). Disfranchised in 1868, W. publishes one weekly newspaper, and has breweries, flour and paper mills, &c. Pop. (1871) 4518. See Parker's *Architectural Antiquities of W.* (Oxf. 1866), and Freeman's *History of W. Cathedral Church* (Lond. 1870).

Wells, Charles Jeremiah, born in London in 1800, was educated at Edmonton with Keats's brother, and Horne the author of *Orion*. With Keats himself he grew intimate, and after that intimacy was snapped by a hoax on the poet's brother, it was in rivalry with Keats that he wrote the little prose volume, simple, idyllic, stillborn—*Stories after Nature* (1822). Two years later appeared *Joseph and His Brethren, by 'H. L. Howard,'* the dramatic poem on which Hazlitt remarked: 'By the by, I have read your poem. It shows great genius; and—I advise you to stick to your profession.' Law was the profession, W. being then under articles to a solicitor; but though he hardly stuck to law, he so far followed the advice that he published no more, beyond a *Sonnet to Chaucer*, one *Story after Nature* more,

and two papers on *Boar-Hunting in Brittany*. *Joseph* lay long neglected, by no man more than by its author, who from fishing and boating in S. Wales betook himself about 1840 to Brittany, there raised, it is said, the dead to life by prayer, and finally settled at Marseille, where he died 17th February 1879. But *Joseph* ere that had been brought from prison by Swinburne, whose attention was called to it by D. G. Rossetti, and who, after vainly dwelling, in his *Essay on Blake*, on the 'dramatic language, passion, and characterisation of this great poem,' had the tardy satisfaction of adding to the reprint (Lond. 1876) an Introduction that commanded from the critics an almost unanimous credit of 'the most Shakespearean drama since Shakespeare's day'—no special recommendation, it would seem, to the reading public. See two interesting articles by Mr. Theodore Watts in the *Athenæum* for April 8, 1876, and March 8, 1879. Communications from E. W. Gosse, W. J. Linton, and R. H. Horne on the same subject appeared in the *Academy* for March 1, April 12 and 19, 1879.

Wells, David Ames, D.C.L., born at Springfield, Massachusetts, U.S., June 17, 1828, graduated (1847) at Williams' College, and at the Lawrence Scientific School, Cambridge (1851), where he was assistant-professor (1851–52), became a practical chemist at Boston (1853), a member of the publishing house of Putnam & Co., New York (1857–58), and associate-editor of the *Springfield Republican* (1858). W. was sent to Europe (1862 and 1867) on commissions for the United States Government, was United States Special Commissioner on Revenue (1866–70), during which time he made fifteen valuable reports, was appointed (1872) lecturer on Political Economy at Yale College, visited Europe (1873), succeeded John Stuart Mill as foreign associate of the French Academy of Political Sciences (1874), received the degree of D.C.L. from Oxford University (1874), and has for many years been a zealous advocate of Free Trade. W. is a varied and industrious litterateur. He has edited the *Annual of Scientific Discovery* (16 vols. Bost. 1850–65); C. Knight's *Knowledge is Power* (1856), and Timb's *Things not Generally Known* (1857); and is the author, among other works, of *The Science of Common Things* (1857); *Elements of Natural Philosophy* (1857); *Principles and Applications of Chemistry* (1858); *First Principles of Geology* (1861), and *Our Burden and Our Strength* (1864).

Welsh Language and Literature. See CYMRIC LANGUAGE AND LITERATURE.

Welsh'pool (so called to distinguish it from other 'Pools'; its Welsh name is *Trellyn*, 'the dwelling on the pool'), a town of Montgomeryshire, N. Wales, near the left bank of the Severn, and 19¾ miles W.S.W. of Shrewsbury by rail. It has a parish church (mostly rebuilt, 1774); a Wesleyan chapel (1864) with a spire 70 feet high; a town-hall and market, Classic in style, with a clock-tower 90 feet high (1874); a library and museum (1874), &c.; and 1 mile distant is Powys Castle, with a fine picture-gallery and beautiful park. The manufacture of flannel and woollen goods is the staple industry of W., which with four other towns returns one member to Parliament. Pop. (1871) 7199.

Wendover, Roger of. See ROGER OF WENDOVER.

Wends (in their own tongue *Serbs*), a branch of the West Slavs, now found in Lausitz, the eastern district of Sachsen-Altenburg, and in the country between the Vistula and Persante (where they are called *Kasuben*), and numbering 140,000, of whom 50,737 were (1875) in Saxon Lausitz alone. The Veneti mentioned by the Elder Pliny and by Tacitus, whom Tacitus wrongly includes among the Germans, are usually identified with the W. Their first seats were the banks of the Niemen and Upper Dnieper, but from the 6th c. their name was extended to the North Slavs generally, who then penetrated Bohemia, and occupied all the lands to the N. on the right bank of the Elbe. These divided into several tribes, of which those on the Lower Elbe first came into conflict with the Germans in the time of Karl the Great, those on the Upper Elbe in that of Heinrich I. With the 10th c. began a long and bloody struggle with the Germans, ending in the 12th c. with the final subjugation and Christianisation of the W. Though under the German Empire, they long maintained a separate position under princes of their own. Their nationality was gradually crushed out by German immigration, disappearing first in the districts of the Main, where they had settled in the 8th c. The last woman who spoke Wendish in the island of Rügen died in 1404. The old language still lingers in Lausitz, where six newspapers are published in it, four of these at Bautzen, of which the chief, the weekly *Serbske Nowiny*, sells 2000 copies. It is edited by J. E. Schmaler, the joint-editor with Haupt of an invaluable collection of Wendish folk-songs and tales. See L. Giesebrecht, *Wendische Geschichten aus den Jahren 780–1182* (3 vols. Berl. 1841–43); R. Andree, *Das Sprachgebiet der Lausitzer Wenden* (Leip. 1873); and *Wendische Wanderstudien* (Stüttg. 1874).

We'ner, Lake, the largest lake in Sweden, lies in the S.W. of the country, between the *läns* of Vermland, Elfborg, and Skaraborg, 144 feet above the sea. Length, 137 miles; breadth, 68 miles; area, 2013 sq. miles; greatest depth, 292 feet. It consists of two parts, Lake W. proper, the larger and N.E. part, and Dalbo Lake in the S.W., separated by Vermland's Näs ('Naze') in the N. and Kallan Island in the S. Numerous rocky islands skirt the shores, which are much broken by inlets. Lake W. is fed by about thirty affluents, the largest of which is the Klarelf (248 miles), and is discharged by the Götaelf, which forms the famous Trollhätta Falls. By the Götha Canal W. is connected with Wetter.

Wen'lock, a town of Shropshire, England, 14 miles S.E. of Shrewsbury by rail. It is a large parliamentary borough, including Madley and Brosely. W. proper, commonly called *Much* or *Great W.*, is a small place, consisting principally of two streets. It has an interesting church and town-hall, and the ruins of a great abbey, founded by a Mercian king about 680. The ruins, which are carefully preserved, are of a 13th c. building. Pop. (1871) of parliamentary borough, 21,208; of the parish of W. 2531.

Wen'lock Forma'tion, one of the great subdivisions of the Silurian system, and lying immediately below the highest or Ludlow group. It takes its name from the town of Wenlock near Shrewsbury, where it is typically developed. The highest member of the W. F. is the Dudley Limestone, which stretches in a ridge nearly 20 miles long through Shropshire. It contains numerous concretions, locally termed 'ball stones,' which are often of gigantic size. Fossils are very abundant and well preserved. The crabs include numerous fine species, some of which occur in masses of great extent. Trilobites are also common, one species, the 'Dudley Trilobite,' or *Calymene Blumenbachii* of palæontologists, being especially well known and characteristic. Crinoids, Brachiopods, &c., are also found in profusion in the Dudley Limestone. Next in order we reach the Wenlock shale, which sometimes attains a thickness of 1000 feet, *e.g.* in Wales, where it is quarried for slates and flagstones. It contains graptolites and a few trilobites. Below the Wenlock shale are the Woolhope beds, consisting of limestones, shales, and grits; and again subjacent to these are the purple 'Tarannon shales,' which last, however, are often referred to the Llandovery group. The whole thickness of the Wenlock rocks is probably about 4000 feet.

Wens are encysted Tumours (q. v.), consisting of obstructed and enlarged sebaceous glands, commonly situated on the scalp, though sometimes on the face, neck, and shoulders. In general, they are better left alone; but they are sometimes so large as to necessitate operative interference. In operations on the scalp, and more especially in the case of W., there is always considerable danger from erysipelas, and hence it is desirable to see that the patient is in good health, and that he does not expose himself injudiciously to any risk, or indulge in any excess, after the operation. The cyst should be removed entire, as any portion left may reproduce the secretion, and prevent the healing of the wound. If there is reason to dread erysipelas, it is safer to remove the wen by caustic, *i.e.*, to destroy the skin over the tumour to a sufficient extent with some caustic, and then either to leave it to discharge itself, or to destroy it by renewed applications of the caustic to its interior.

Wen'tletrap (*Scalaria*), a genus of *Gasteropodous* Mollusca, belonging to the family *Turritellidæ* (q. v.). The shell is turreted, ribbed externally, and has many whorls. The aperture is round. Of the wentletraps the most famous species is the *S. pretiosa*, or Precious W., a fine specimen of which sold in the days of conchological mania for £50 and upwards. The precious W. is of

pure white colour, and occurs in tropical seas. The Common W. of the British coasts is the *S. communis*, found of a dull-white hue, but often of a brownish colour. In the true W. the whorls are not united; the shells which resemble them, and have contiguous whorls, being designated 'False Wentletraps.'

Wer'dau, a town of Saxony, on the Pleisse, 49 miles S. of Leipzig by rail. It is chiefly notable for its manufactures. Woollen goods, nets, machinery, and tiles are made, and there are also iron-foundries, flour-mills, &c. Pop. (1875) 11,689.

Wer'den, a town of Rhenish Prussia, on the Ruhr, 16¾ miles N.E. of Dusseldorf by rail. It has a Catholic and an Evangelical church, and manufactures of cloth, felt, shoes, brushes, locks; also spinning, weaving, dyeing, and brewing. There are coal-mines in the neighbourhood. Pop. (1875) 6746. In the Abbey of W., founded in 778, there was discovered in the 16th c. the famous *Codex Argenteus*. See ULFILAS.

Wer'geland, Henrik Arnold Thaulow, a Norwegian poet, was born at Christiansand, 17th June 1808, and graduated at Christiania in 1829. His early sympathies were fired by the July Revolution in France, the struggles of the Poles, and the rise of Democratic sentiment in Norway. Liberty and Reason became his guiding-stars in politics and religion, and he followed their guidance with all the force of genius and the enthusiasm of a poet. His first works were the so-called farces of 'Siful Sifadda,' *Ah!* (1827), and *Irreparabile Tempus* (1828), and *Digte, förste Ring* (1829). In the latter year W. entered public life as one of the most eloquent opponents of the Conservative party. His religio-philosophical poem, *Skabelsen, Mennesket, og Messias* (1830), called forth the sharp criticism of Welhaven (q. v.) in 1832. W. was for some time editor of *Folkebladet*, and from 1835 to 1837 of *Statsborgeren*; and after the dissolution of the popular parliament in 1836 published a large number of violent party songs and pamphlets. His *Digte, anden Ring*, and the drama *Barnemordersken* (1835), are full of the noblest lyric diction, and show a great advance on his earlier works in clearness. But W.'s style was at best too difficult to be popular with the vulgar, as his genius was too original to be the organ of any party. The friendly offices of King Karl Johan gradually won him over to the court; in 1839 a pension from the king succeeded in drawing him from the field of politics. To this later period belong some of his best poems, *Jan van Huysums Blomsterstykke, Svalen, Jöden, Jödinden*, and *Den Engelske Lods*. He died of consumption at Christiania, August 12, 1845. His poems are published in 9 vols. by H. Lassen (1852–59), and a selection, *Udvalgte Skrifte*, appeared in 1859. See Gosse, *Northern Studies* (Lond. 1879).

Wer'geld (from *wer*, 'a man,' and *geld*, 'money'), the Old English title of a widespread institution, extending perhaps beyond the Aryan family, which, appealing from love of vengeance to love of gain, allowed a wrong-doer to purchase the life he otherwise had forfeited under a sterner code. It offers itself in its rudest form in the Homeric poems, where the kinsfolk of a slaughtered man seem only to have been bound by custom to take the proffered atonement, nay sometimes are praised for its rejection (*Il.* ix. 628, and vi. 45); in the earliest glimpses of Teutonic law a great advance may be discerned. For here not only has the state interfered to enforce the acceptance of the atonement and assess its amount, but it looks on a crime as done to itself, and so claims for its king or other head a share of the W. Both in the laws of Æthelbert and in those of Ælfred three centuries later we find an elaborate scale of prices, so much for a Briton, so much for an Englishman, so much for a churl, so much for a thegn, so much at last for the king himself. And as the price must always be paid to him who had borne the loss, of a slave for instance to his master, so the king's W. had to be paid both to his kinsfolk and his commonwealth; and English history records two cases where the invading avenger of a royal kinsman slain was stayed by the payment of W.—by the Kentish men for the slaying of Mul, by the Mercians for the slaying of Ælfwine of Northumberland. With the severance of criminal from civil law, and the superseding of compensation by punishment, the W. grew obsolete, and the last recorded instance of its use was when in the reign of Edward IV. Lord Berkeley made the widow of Lord Lisle a money payment for her husband's death. See Freeman's *Comparative Politics* (Lond. 1873).

Wer'ner, Abraham Gottlob, a celebrated mineralogist and geologist, was born September 25, 1750, at Wehrau in Ober-Lausitz, where his father was director of a smelting-work. In 1769 he entered the mining school at Freiberg, studying law and the natural sciences at Leipzig, and in 1775 became professor of mineralogy at Freiberg, where he soon formed a school of geologists and mineralogists who diffused his views over Germany. In this way, though he himself published comparatively little, his theories exercised a powerful influence upon the science of the day. He systematised mineralogy, arranging minerals mainly by their external characters, and laying small stress upon their chemical constitution. From a study of the Tertiary formations in his own district, beyond which he hardly ventured, he generalised a theory of the formation of strata, which his disciples strove hard to reconcile with the geological structure of other and distant regions which they visited. The gist of this theory was that all rocks were sedimentary. His system was vitiated, however, by his basing his classification chiefly upon mineralogical characters, giving small heed to fossil evidences)see GEOLOGY). W. died at Dresden, June 30, 1817. His chief works are, *Ueber die Aüsseren Kennzeichen der Fossilien* (1764), *Kurze Klassifikation und Beschreibung der Gebirgsarten* (1787), *Neue Theorie über die Enstehung der Gänge* (1791), and *Verzeichniss des Mineralienkabinets der Berghauptmann's Pabst von Ohain* (2 vols. 1791–92). See his Life by Frisch (1825) and Configliachi (1827), and Hasse's *Denkschrift zur Erinnerung an W.* (Leip. 1848).

Wernigero'de, a town of Prussia, province of Sachsen, belonging to the counts of Stolberg-Wernigrode, on the slopes of the Harz Mountains, at the confluence of the Zilligerbach and the Holtzemme, 40 miles S.W. of Magdeburg. It has a beautiful 'schloss' containing a library of 69,000 vols., specially rich in collection of Bibles and Hymnologies, a gymnasium, three churches, a Rathhaus dating from the 14th c., and built, as are also many of the private houses, in a picturesque Gothic style, a thiergarten or park, an orphanage, &c. W. has manufactures of linen, cloth, tobacco, and bricks. Pop. (1875) 7580. See Förstemann, *Die Grafl. Stolberg'sche Bibliothek in W.* (Nordh. 1866).

Wer'wolves (Teut. *wer-wulf*, 'man-wolf,' whence Old Fr. *garoul*, now pleonastically *loup-garou*) are defined in Verstegan's *Restitution of Decayed Antiquities* (Lond. 1628) as 'certain sorcerers, who, having anointed their bodies with an ointment which they make by the instinct of the devil, and putting on a certain enchanted girdle, do not only unto the view of others seem as wolves, but to their own thinking have both the shape and nature of wolves, and do dispose themselves as very wolves in worrying and killing, and most of human creatures.' The belief in such monsters was rifest in the great witch era of the 16th c., when the parliament of Franche-Comté passed a law for their expulsion (1573), and when near Köln one Peter Stump, 'for being a werwolf, and having killed thirteen children, two women, and one man, was put unto a very terrible death' (1589). But it existed in ages far remote (*cf.* Herodotus, iv. 105; Virgil, 6th Ecl., &c.), and even to-day is cherished by French and Russian peasants, the latter dividing *volkodlaks* (lit. 'wolf-hides') into voluntary and involuntary undergoers of the transformation. In England, where wolves have been long extinct, a cat or hare usurped their place in the superstition, the name of werwolf only surving in *Kempion* and a few such ancient ballads, while *William and the Werwulf* was rendered from a French romance. At Thurso, an honest fellow, harassed by witches under the form of cats, cut off the leg of one less nimble than the rest; it changed to a woman's leg, and next morning he found the crippled hag, its owner. On a like incident turn many Continental werwolf tales; and similarly the man-hyænas, lions, tigers, or panthers of Asia, Africa, and South America, present a similar uniformity of principle. The Werwolf Doctrine is by Tylor regarded as 'substantially that of metempsychosis, backed by Lycanthropy (q. v.), the mental delusion whose victims imagine themselves transformed into wild beasts. Cox, on the other hand, refers it to the Lycaon myth, arising from a confusion of the Gr. *leukos*, 'bright,' with *lykos*, 'wolf,' an ingenious theory, which fails, however, to account for the wide extension of the belief beyond the Aryan race. See Hertz, *Der Werwulf* (Stuttg. 1862), Baring-Gould's *Book of W.* (Lond. 1865), vol. i. of Cox's *Aryan Mythology* (Lond 1870); vol. i. of

Tylor's *Primitive Culture* (Lond. 1871), Ralston's *Songs of the Russian People* (Lond. 1872), and *Russian Folktales* (Lond. 1873).

We'sel, a strongly fortified town of Prussia, at the confluence of the Rhine and Lippe, 32 miles N. of Dusseldorf by rail. It has five churches, among them St. Willibrord's (1181–1521), and the Metenakirche, with a tower 334 feet high (1472); a Gothic Rathhaus (1390–96), lately restored and adorned with modern statues, a government house, built (1417) by the Archduke Adolf of Kleve, and now the residence of the commandant of the garrison, a gymnasium and other schools, &c. The fortifications consist of various bastions, ravelines, and other outworks, a citadel at the junction of the Rhine and Lippe, and several forts, of which one is on the left bank of the Rhine. The garrison consists of 5 battalions of infantry with artillery. In front of the Berlin Gate stands a monument (1835) to eleven Prussian officers, here shot by Napoleon in 1809. W. has sugar refineries, manufactures of stearine, paper, tobacco, and nails, some shipbuilding, and an active river trade in fish and timber. Pop. (1875) 19,104. Originally a free imperial town, it passed about 1220 to the counts of Kleve, but continued to enjoy many special privileges. From 1614 onwards for two centuries it shared the chequered fortunes of the rest of the Rhine towns. By the Peace of Paris W. was assigned to Prussia. See Wolter's *Reformationsgeschichte der Stadt W.* (Bonn 1868).

We'ser (Lat. *Visurgis*), a river of Germany, formed at Munden in Hannover by the union of the Werra and the Fulda, the former of which rises in the Thuringer Wald (q. v.), the latter in the Rhongebirge. The united stream takes a northward course through Hannover, forming for a short distance the boundary between Westphalia and Brunswick. After passing Bremen it forms the E. boundary of Oldenburg, and enters the North Sea by a shallow estuary E. of the Elbe mouth. Its length is 270 miles. Large ships do not ascend above Bremerhafen, but smaller vessels go up as far as Bremen. A canal connects the W. with the Elbe.

Wes'ley, John, founder of the English Methodists, was born, 17th June 1703, at Epworth, in Lincolnshire, where his father was clergyman. He was educated at the Charterhouse school, and in his seventeenth year entered Christ Church, Oxford. In 1726 he was elected a fellow of Lincoln. After officiating for a short time as his father's curate, W. returned to Oxford, where he became a member of a little devotional society which his brother, **Charles W.** (1708–1788, still remembered for his noble *Hymns*), had established. This was the first germ of Methodism (q. v.). At this time the two Wesleys were much under the influence of William Law (q. v.), author of the *Serious Call*. On 14th October 1735 they sailed for Georgia, bound on mission work. John W. had much intercourse with the Moravians during his sojourn in America, and on his return in 1738 this was continued, till two years later he separated from them. Although to all appearance he had long been an earnest, God-fearing man, he has himself given us the exact date of his conversion—the evening of the 24th May 1738, at a quarter to nine evening, when he felt an irresistible assurance that Christ had taken away his sins. Certainly from this period his profound religious activity begins. He travelled for a while preaching 'repentance and judgment to come,' and when the cold formalism of the established religion quickly changed into angry opposition, he was obliged in self-defence to form his adherents into a regular organisation—in other words, to establish a new sect. On 12th May 1739 the first Methodist chapel was founded. The rest of W.'s life was given to continuous and earnest work in the cause which he had made his own. During over half a century of eager activity 'it was computed that he travelled about 225,000 miles and preached more than 40,500 sermons, not including addresses, exhortations, and speeches.' He died March 2, 1791, and was buried in the City Road Chapel. W. held the evangelical creed with but few modifications, though he recoiled from the extreme deductions of Calvinism. But he breathed into this creed the breath of life. His sermons were simple, straight, direct appeals, spoken from the heart to the heart, without the waste of one superfluous word; hence their extraordinary effect. His power, in short, was that not unfitly named 'revivalist'; what men already held as an intellectual belief, he made them hold as a living, working reality. *The Works of the Rev. J. W.* were collected and published in 16 vols., 1809, 3d ed. 14 vols. 1829–31. See Southey's *Life of W. and Rise and Progress of Methodism* (2 vols 1820; new ed. Bohn, 1864) and Miss Wedgwood's *Life of W.* (1 vol. Lond. 1870), and Tyerman's *Life and Times of W.* (Lond. 1870, 3d ed. 1876).

Wesley'an Conference. See METHODISTS.

Wesley'an University, The, opened at Middletown, Connecticut, U.S., in 1833, occupies the former buildings of the American Literary, Scientific, and Military Academy, which with recent additions comprise a library of 20,000 volumes, a chapel erected as a memorial of the eighteen students and alumni who fell in the Civil War, laboratories, the Orange Judd hall of natural science, &c. There are three courses: Classical, Latin-Scientific, and Scientific. Since 1872, ladies have been admitted to the W. U., which in 1876 had 16 professors and instructors, and 176 students (9 ladies).

Wessel, Johann, called **Gansfort**, one of the 'Reformers before the Reformation,' was born about 1420 at Groningen, studied Greek and Hebrew and the Platonic philosophy at Koln, taught philosophy there and elsewhere, and died 4th October 1489 at his native town. W. was named by his admirers *Lux mundi*, by his adversaries *Magister contradictionum*. He was a man of a powerful intellect, an eager opponent of the scholastic philosophy, and (for his time) a bold and original speculator. After his death a great part of his writings were condemned by the Church. Luther edited a part of his works under the title of *Farrago Rerum Theologicarum* (Wittenb. 1522). A complete edition was edited by Joh. Lydius (Amsterd. 1617). See his Life by Ullmann (Hamb. 1834), Bahring (Bielef. 1846), and Friedrich (Regensb. 1862).

Wessex. See HEPTARCHY.

West, Benjamin, an Anglo-American painter, was born of a Quaker family at Springfield, Pennsylvania, 10th October 1738. He showed great precocity in the use of water-colours and at the age of sixteen practised portrait-painting around Philadelphia. After painting for some time in New York, he went in 1760 to Italy, where he studied till 1763, when he settled in London. He soon acquired a high reputation for his portraits, and was introduced to King George III., whose patronage he enjoyed for forty years. On the death of Dr. Johnson in 1791 he was elected President of the Royal Academy, and occupied the chair, with a short interval, till his death, which took place in London, 11th March 1820. He was buried with great pomp in St. Paul's. W. is criticised somewhat harshly by Dr. Waagen, who considers that he valued nature less than academic rule, while admitting the superior quality of his drawing, composition, and chiaroscuro. Among his principal works are the 'Death of Wolfe,' 'Battle of the Boyne,' 'Battle of La Hogue,' 'Christ Before Pilate,' 'Orestes and Pylades,' 'Christ Healing the Sick,' 'The Last Supper,' 'Death on the Pale Horse,' 'Moses Delivering the Laws,' 'Alexander the Great with his Physician,' 'Agrippina with the Ashes of Germanicus,' and 'Cromwell Dismissing the Symbols of Royalty.' W. also painted several pieces for the court chapel at Windsor, and designs for the windows executed by Forest in 1792–96, as well as several pieces for the castle. See Galt's *Life and Studies of B. W.* (Lond. 1820), and Waagen's *Treasures of Art in Great Britain* (3 vols. Lond. 1854).

West Brom'wich, one of 'the Black Country' towns in S. Staffordshire, England, on a barren heath 5 miles N.W. of Birmingham by rail. It is the centre of a productive mining district, and has important mineral industries, manufacturing engine-boilers, boiler-plates, ship-tanks, anvils, anchors, gasometers, gas-pipes, lamp-posts, railings, locks, coach furniture, &c. There are large smelting furnaces, foundries, malt and lime kilns, chemical works, brick-yards, &c. The town is of recent and rapid growth, and has several handsome edifices. The public buildings (erected in 1875 at a cost of £30,000) comprise a town-hall with a fine organ (1878) and a massive tower 130 feet high, a market-hall (151 feet by 90), free library, public baths, &c. Besides 11 Established churches, there are numerous Dissenting chapels; the parish church was restored (1876) at a cost of £3000, and a second Roman Catholic church was erected in 1877. Pop. (1871) 47,981.

West'bury, a town of Wiltshire, England, 26 miles N.W. of Salisbury by rail. The fine church of All Saints, with a hand-

some tower, dates from the 13th c., and is a good specimen of the Perpendicular style. Woollen cloth is manufactured, but agriculture forms the main industry. More recently, discoveries of ironstone in the vicinity have led to the development of the iron trade. Pop. (1871) 6396. W. is a place of great antiquity, and Roman remains have been found in the district. Bratton Castle in the neighbourhood occupies, it is supposed, the site of a British encampment.

West'cott, Brooke Foss, D.D., born near Birmingham in January 1825, obtained a scholarship at Trinity College, Cambridge, and having gained many university distinctions graduated B.A. (1848) as twenty-third wrangler and bracketed senior classic. Elected a fellow of Trinity in 1849, he next year took orders, and was an under-master at Harrow from 1852 to 1869, when he received a Peterborough Canonry. In 1870 he became Regius Professor of Divinity at Cambridge, in 1875 an honorary chaplain to the Queen, and in 1879 a chaplain in ordinary, being besides a member of the Revision Company. W. is author of a *History of the Canon of the New Testament* (1855; 4th ed. 1875), *Introduction to the Study of the Gospels* (1860; 5th ed. 1875), *General View of the History of the English Bible* (1869; 2d ed. 1872), *On the Religious Office of the Universities* (1873), &c.

West'ern Austra'lia, a British colony embracing the whole of the Australian continent W. of 129° E. long., and lying between 13° 44'–35° S. lat. It is the largest of the Australian colonies, having an extreme length from N. to S. of 1280 miles, and an average breadth of 650 miles, with an area of 1,057,250 sq. miles, or more than eight times that of the United Kingdom. Its coast-line exceeds 2000 miles in length, and is indented by several large bays while the northern portion is fringed by numerous islands and coral reefs. The country is usually level or undulating, and the mountain-ranges are few, scattered, and of low elevation, the chief being the Darling Range (q. v.), in the S.W., whose maximum height is 3500 feet. For a distance of 200 miles inland the country is usually covered with wood, varying from scrub to forests of magnificent trees, of which the Jarrah (q. v.) is the most noteworthy. E. of this region the ground is usually sandy or stony, bare and desert in the extreme, at most supporting only stunted scrub or scanty spinifex, and here and there studded with shallow salt lagoons. The rivers of W. A. are of small size, and few of them are permanent. The chief are the Swan (q. v.), Blackwood, Murchison, Gascoyne, and Fortescue. The climate of the extra-tropical portion of the colony is exceedingly salubrious, and the extremes of drought and flood common in the other Australian colonies are unknown in W. A. Severe N.W. gales and occasional hot winds from the interior are the chief drawbacks to the climate. The settled portion, which occupies the S.W. part of the colony, and measures about 600 by 150 miles, contains many fertile tracts, on which all European fruits grow to perfection, and fine wheat is also produced. In 1877 the yield of wheat was 251,174 bushels, of barley 77,324, of oats 18,060. Much of the colony is well adapted for grazing, and although the presence of poisonous plants somewhat hinders stock-raising, W. A. in 1877 had 30,691 horses, 52,057 cattle, 797,156 sheep, and 18,942 pigs. Gold, believed to exist in abundance, is worked to a small extent; the rich deposits of lead and copper are being remuneratively wrought; and zinc, iron, and coal are also plentiful. A flourishing pearl-shell fishery is carried on along the coast, chiefly by Malay labour. In 1877 the total value of the imports of W. A. was £362,707, and of the exports £373,352, the chief items of the latter being wool, timber, pearl-shell, tortoise-shell, sandalwood, gums, guano, and horses. At the close of 1877 there were 68 miles of railway open, and 25 more in course of construction, and 1567 miles of telegraph were in operation. The pop., exclusive of aborigines, was officially estimated at 27,838, and the public debt amounted to £161,000.

W. A. was taken possession of by a British military detachment in 1826, and three years later the first settlement was made on the Swan River, whence the country was for years known as the Swan River Settlement. At the request of the colonists the transportation of convicts to W. A. was commenced in 1850, and continued until 1868, when the representations of the other Australian colonies caused it to be stopped. The government is administered by a Governor appointed by the Crown, and assisted by an Executive Council of 5 members, as well as by a Legislative Council of 21 members, of whom 7 are nominated by the Crown, and the remainder elected by the constituencies. The capital is Perth (q. v.), and the other principal settlements are Freemantle, Geraldton, Albany, and King George's Sound (q. v.).

West'field, a town of Massachusetts, U.S., 9 miles W. of Springfield by rail. It has 9 churches, a public library, and 1 weekly newspaper. The waterworks of W. are very large. W. has great whip-factories, turning out annually £160,000 worth of whips, extensive cigar-manufactures—18,046,000 cigars having been made in 1875—paper-mills, &c. It is also noted for its manufacture of church-organs and piano-legs. In 1876 the valuation of W. amounted to $7,544,369. Pop. (1876) 6242.

West Indies, a name given to that archipelago which stretches from the channel of Yucatan (q. v.) to the Gulf of Maracaybo (q. v.). The name arose out of the belief of Columbus that, by his voyage across the Atlantic, he had reached by a westward route the famous and reputedly opulent empire of India. See ANTILLES, and the articles devoted to the various islands of the group.

West'macott, Sir Richard, R.A., an English sculptor, was born in London, July 1755, and in 1773 went to Rome, where he became a favourite pupil of Canova, and gained a gold medal for the best piece of statuary. He also obtained a prize for sculpture at Florence, and was elected a member of the academy there. On his return to England (1798) he rapidly obtained a high reputation, which was confirmed by the statue of Addison (1806) in Westminster Abbey. W. became an R.A. in 1816, succeeded Flaxman as professor of sculpture at the Royal Academy in 1827, and was knighted in 1837. He died 1st September 1856. Among his chief statues, most of which are in Westminster or St. Paul's, are those of Sir Ralph Abercromby, Lord Collingwood, Pitt, Fox, Erskine, Nelson, Warren Hastings, George Canning (in St. Margaret's Church), George III. (on Snow Hill), and Lord W. Bentinck (in Calcutta). Other works are the Achilles in Hyde Park, erected in honour of Wellington by the ladies of England at a cost of £10,000; Cupid and Psyche; the groups on the Marble Arch and in the British Museum; the large Waterloo Vase in the National Gallery. W.'s art is 'classical' or conventional, but what it lacks in originality of design is in part at least atoned for by delicacy of finish, harmony of composition, and by truth and vigour of anatomy.—**Richard W., R.A., F.R.A., R.S.**, son of the preceding, was born in London 1799, studied in Italy 1820–26, was elected R.A. in 1849, and succeeded his father as professor of sculpture in 1857. Among his best works, which are chiefly mythological and religious, are 'Venus and Ascanius,' 'The Cymbal-Player,' 'A Girl and Fawn,' 'Venus Instructing Cupid,' 'Paolo and Francesco,' the bas-reliefs 'The Blue Bell,' 'Go and Sin no More,' 'The Angel Watching,' and monumental figures of Archbishop Howley and the Earl of Hardwick. Besides *Lectures*, and the article on Sculpture for the *Encyclopædia Britannica* (8th ed. 1857), he published a treatise *On Colouring Statues*, and a *Handbook of Sculpture, Ancient and Modern* (Edin. 1864). He died at Kensington, 19th April 1872.

West'meath, a midland county of the province of Leinster, Ireland, is bounded N. by Cavan, N.E. and E. by Meath, S. by King's County, W. by Roscommon, and N.W. by Longford. Area, 453,468 acres; pop. (1851) 107,510, (1871) 78,432, a decrease due to emigration. With a gently-undulating surface, nowhere exceeding 710 feet of elevation, W. forms part of the central Carboniferous limestone district. The water-area of 22,427 acres belongs chiefly to the basin of the navigable Shannon (q. v.), which, widening into Lough Ree, forms the western boundary; but on the E. rise numerous small tributaries of the Boyne. The soil, in the E. a heavy loam, becomes lighter to the W., and the climate is equable, the rainfall of 1877 being 45·51. Of 93,409 acres under crops in 1878 (127,214 in 1853), 125 were in wheat, 22,941 in oats, 828 in barley, bere, and rye, 11,146 in potatoes, 5698 in turnips, and 49,296 in meadow and clover, while woods and plantations covered 8229 acres in 1877. The live-stock included (1878) 12,463 horses and mules, 4266 asses, 98,160 cattle, 149,775 sheep, and 15,215 pigs, and the rateable valuation was £315,544. The population is almost wholly agricultural and Catholic, there being in 1871 but 6667 Protestants; and of the total 31 per cent. were illiterate, though W. had 177 schools. Athlone (q. v.) and Mullingar (q. v.) are the only towns in the county, which returns two members to Parliament. Anciently it formed part of the kingdom of Meath (q. v.), from which it was separated in 1543.

West'minster, The City of, an important section of the metropolis of the United Kingdom, is bounded on the E. by the city of London and on the S. by the river Thames. From Tottenham Court and by Finsbury Road westwards to Kensington Gardens it is separated from the parliamentary borough of Marylebone by Oxford Street, while its western boundary is a line crossing the centre of the Serpentine in Hyde Park and reaching the river at Chelsea Hospital. In 1871 it contained 26,400 inhabited houses, and a pop. of 253,985 souls. It returns two members to Parliament. Historically and architecturally it is full of an interest which culminates in the venerable pile known as Westminster Abbey, around which the city itself sprung. The foundation of the first Abbey on a spot formerly surrounded by the waters of the Thames, and called Thorney Island, is involved in mystery, but here was certainly one of the earliest Christian churches in England. Sebert, King of the East Saxons, who died in 616, is believed to have completed a sacred edifice dedicated to St. Peter, which was destroyed by the Danes. Edward the Confessor in its place built a structure of great splendour for his time, and endowed it with a charter of ample powers and privileges. Henry III. pulled down a portion and enlarged the plan of this ancient Abbey, adding a chapel dedicated to the Virgin and the 'incomparable' chapter-house. Henry VII. built the magnificent chapel to the E. of the Abbey which bears his name. After his reign the building fell into decay, until renovated by Sir Christopher Wren, who designed the upper part of the two western towers. The restoration of the chapter-house was undertaken by Sir Gilbert Scott in 1863. The Abbey is in the form of a Latin cross, its exterior length being 416 feet, or including Henry VII.'s chapel, 530 feet. Its interior length is 375 feet, and its greatest interior breadth 200 feet. The breadth of the nave and aisles is 75 feet, and their interior height, to which the abbey owes much of its stately appearance, is 101 feet. The best view of the abbey is from the W. door between the towers. In the interior are a noble range of pillars terminating towards the E. by a sort of semicircle inclosing the chapel of Edward the Confessor. The fabric is lighted by a range of windows supported by galleries of double columns on the arches of the pillars, by an upper and under range of windows, and 4 capital windows, the whole of the lights being admirably arranged. 22 windows are enriched with stained glass. The new choir, 155 feet by 35 feet, was executed in 1848. The 52 stalls exhibit a great variety of carving and tracery. The reredos, completed under the direction of Sir Gilbert Scott, is an elaborate and splendid work. The names of the various chapels, beginning from the S. cross and passing round to the N. cross, are in order as follows:—(1) St. Benedict; (2) St. Edmund; (3) St. Nicholas; (4) Henry VII.; (5) St. Paul; (6) St. Edward the Confessor; (7) St. John; (8) Islip's Chapel, dedicated to St. John the Baptist; (9) St. John, St. Michael, and St. Andrew. The Chapel of Henry VII. is adorned without with 16 Gothic towers, beautifully ornamented and jutting from the Abbey at different angles. Here is the magnificent tomb of that monarch and his queen. In the S. transept is the well-known Poet's Corner. Every English sovereign since the Conquest has been crowned in Westminster Abbey, and the coronation-chairs and the coronation-stone of Scotland are in the Chapel of Edward the Confessor. 13 sovereigns (George II. being the last) and 14 queens are buried in its precincts. Here also are the remains of Chaucer, Spencer, Ben Jonson, Dryden, Cowley, Addison, Congreve, Prior, Gay, Dr. Johnson, Garrick, Sheridan, Campbell, and Macaulay; of Handel, Blow, and Purcell; of Pitt, Fox, Wilberforce, Grattan, Canning, and Peel; and a multitude of the illustrious departed. Palmerston, Charles Dickens, Lytton, and Livingstone are among the latest of the glorious company. There are also memorials to Shakespeare, Milton, Goldsmith, Thackeray, and many others whose remains lie elsewhere. Some of the monuments, such as that to John, Duke of Argyll, are very imposing. The Abbey fills a great place in the political and religious history of England. The Chapter-House was used for three centuries as the meeting-place of the House of Commons, and was thus the cradle of representative government, and the scene of the chief acts which laid the foundation of the civil and religious liberty of England. The Westminster Assembly of Divines sanctioned in the Abbey the Confession of Faith, which is the recognised creed of the Presbyterian Church (1643-52), and the final alterations on the Book of Common Prayer were made by the Bishops in the Jerusalem Chamber in 1662. Roman, Anglican, and Puritan theologians have in turn preached in these walls. In recent times, under the enlightened rule of Dean Stanley, the national character of the Abbey has been well maintained. Officially called the Collegiate Church of St. Peter, it is governed by the Dean, a chapter of 8 prebendaries, and other officers. See *History and Antiquities of Abbey Church of St. Peter, Westminster*, by John Neale and Edward Brayley (2 vols. Lond. 1818), *Historical Memorials of Westminster Abbey*, by Dean Stanley (4th ed., Lond. 1876), and the *Historical Description of Westminster Abbey*, printed for the Vergers (1878). Adjoining the Abbey is the ancient *Church of St. Margaret's*, dating from the reign of Edward I., where members of the House of Commons are supposed to attend officially at the beginning and end of the Parliamentary session; and *Westminster School*, which takes rank as one of the greatest of English Public Schools (q. v.). *Westminster Hospital*, which stands in Broad Sanctuary, was founded in 1715, the present building having been erected in 1834. *Westminster Hall*, attached to the Houses of Parliament, is a place of great historic interest. It was erected by Richard II., is 90 feet high and 290 feet long by 68 feet wide. Internally roofed by thirteen great ribs of timber, it has one of the largest roofs in the world unsupported by pillars. Here Wallace, Sir Thomas More, the Protector Somerset, Strafford, Charles I., and the three Jacobite lords in 1745, were condemned to death; here Cromwell was inaugurated Lord Protector; and it is the scene of the famous trials of the seven bishops and of Warren Hastings. At the coronation of George IV. a grand coronation banquet was given within its walls. The higher law-courts of England, which have met here so long, are about to be transferred to new courts in the Strand. The old *Houses of Parliament* were destroyed by fire in 1834, and the present magnificent Gothic edifice, facing the river Thames and forming the most splendid legislative building in the world, was built from the designs of Sir Charles Barry. 900 feet long by 300 wide, it covers 8 acres, has 100 staircases, 1100 apartments, and 2 miles of corridors, whilst it is warmed by 16 miles of steam-pipes. The original cost of the building was £2,000,000, but this sum has been doubled by improvements and embellishments. It is built of Yorkshire limestone, which shows an unfortunate tendency to decay, to remedy which various plans have from time to time been tried. The river terrace is of Aberdeen granite, and the river frontage is decorated with rows of statues and shields of arms of the Kings and Queens of England. The proposed land frontage, with a façade to enclose the law-courts, has not yet been completed. The central tower is 300 feet high; the splendid Victoria tower to the S.W. (completed in 1857), where the Acts of Parliament are stored, is 346 feet high; and the clock tower to the N. surmounted by the belfry is 320 feet high. The clock has four faces, each 22 feet in diameter; the bell weighs 9 tons. At the Westminster Bridge end are the apartments of the Speaker and the Serjeant-at-Arms; at the other end those of the Usher of the Black Rod and the Lords' Librarian. Above these are long ranges of rooms for parliamentary committees. The Houses of Lords and Commons, in the centre of the building, are separated by corridors and the great octagon hall. The House of Peers (97 feet long, 45 feet wide, and 45 feet high) is one of the most magnificent chambers in the world. The House of Commons is cramped for room, being only 62 feet long, its other dimensions being the same as the House of Peers. The Royal entrance is under the Victoria tower, leading to the Robing Room and the Royal Gallery adjoining the House of Peers. There are a number of spacious and beautiful halls and courts devoted to various purposes, and adorned by many splendid paintings, statues, and frescoes. The public are admitted to the Houses of Parliament on Saturdays by tickets obtained on the spot. *Westminster Bridge* (built 1856-62) has a very graceful appearance. It stands on seven arches of iron, is 1160 feet long and 85 feet wide. The *Victoria Embankment* (finished in 1870), from the Bridge to Blackfriars, is one of the greatest modern improvements in the C. of W. The magnificent *Public Offices* in Whitehall, accommodating the Foreign, India, Colonial, and Home Offices, were designed by Sir Gilbert Scott.

West'moreland, one of the northern counties of England, is bounded on the W. and N.W. by Cumberland, on the S.W. and S. by Lancashire, on the S. and E.N.E. by Yorkshire, and

on the N.E. by Durham. Area, 500,906 acres, of which in 1878 16,043 were under oats, 2370 under barley, and 1088 under wheat, in all 19,688 under corn crops, as against 10,317 under green crops (7861 under turnip and 1779 under potatoes), 15,892 under grasses, and 196,185 of permanent pasture. In the same year the number of horses returned was 8158, of cattle 61,586, of sheep 348,174, and of pigs 8158. The country is mostly mountainous, being traversed in a general direction from N. to S. by various ridges belonging to the Pennine and Cumbrian chains, the two being divided by the valley of the Eden, which, with the Lune, the Kent, the Winster, and the Rothay, conveys the drainage of the country into the Morecambe Bay. Geologically W. is divisible into three districts—the N.W., whose prevailing formation is green slate and porphyry; the S.E., characterised by upper slates of the Silurian system, and the N.E., including the basin of the Eden, where Carboniferous rocks occur, and in the neighbourhood of Dufton and Orton lead and copper mines, 1372 tons of lead being extracted in 1874 from the five lead mines at Dufton. Three collieries also yielded 1791 tons in 1878. W., however, owes its chief celebrity to its mountains and lakes, though Helvellyn and Windermere belong partly the one to Cumberland and the other to Lancashire, but Crossfell, Bowfell, High Strut, Birbeckfell, Ulleswater, Grasmere, Rydal, &c., are well known to the tourist. The climate is moist, Kendal having the reputation of being the rainiest town in England, and the snow-storms in winter have more than once proved fatal to unwary mountaineers. The soil in the valleys is mostly a deep gravelly mould, very favourable to the growth of turnips, but towards the E. and N. it inclines more to clay. The chief towns are Appleby, Ambleside, Kendal, and Brough. W. returns three members to Parliament. This county seems to have played a part of some little importance in Roman and Old English times, to judge from the remains which have been discovered at Brough and elsewhere, but in the more historic centuries it does not come prominently forward. The lake district is indissolubly associated with the poet Wordsworth, on the relation of whose poems to the scenery of the district see Professor Knight's *English Lake District as interpreted in the Poems of Wordsworth* (Edin. 1879). Compare also J. Lawson on the *Geography of W.* (Lond. 1878).

Westpha'lia (Ger. *Westfalen*), a province of Prussia, bounded N. by Holland and the province of Hannover, E. by Hannover, Schaumburg-Lippe, Braunschweig, Waldeck, and Hessen-Nassau, S. by Hessen Nassau and the Rhine Province, and W. by Holland and the Rhine Province. Area 7799 miles; pop. (1875) 1,905,697 (806,464 Protestants, 949,118 Catholics, 17,245 Jews). It is divided into three districts—Münster in the N.W., Minden in the N.E., and Arnsberg in the S. The northern half is generally flat, the southern covered with ranges of hills of no great elevation, offshoots from the Harz Mountains. The chief ranges are the Weser chain, the Teutoburgerwald, which forms the watershed between the Rhine and the Lippe, and the Suntelgebirge, extending from Osnaburg into Schaumburg-Lippe, crossed 5 miles S. of Minden by the famous pass, the *Porta Westphalica.* The chief rivers are the Weser, with the Diemel and Werre, the Ems, Lippe, and Ruhr. The soil in the N. is sandy, with extensive tracts of heath and swamp, in the S. is more fertile. About 41·6 of the surface is under cultivation, 27·9 under wood, and 17·3 under pasture. The chief crops are corn, buckwheat, potatoes, leguminous fruits, flax, hemp, hops, and tobacco. In 1873 there were within W. 118,073 horses, 567,975 cattle, 484,151 sheep, 251,840 pigs, 171,243 goats, and 95,668 hives of bees. W. is rich in minerals. In 1875 the yield was, coal, 214,980,503 cwts.; iron ores, 15,984,597 cwts.; zinc ores, 630,487 cwts.; copper ores, 787,636 cwts., and of lead ores, quicksilver, antimony, and pyrites, 2,361,051 cwts. Active manufactures are carried on of cottons, linen, paper, glass, leather, cordage, sail-cloth, powder, potash, sugar, soap, pottery, cigars, and wooden wares. The chief articles of export are linens, cottons, coal, iron, timber, sausages, and the well-known Westphalian hams. See Freiligrath and Schücking, *Das Malerische und Romantische W.* (2d ed. Paderborn 1871). The name *W.* formerly signified the district in the N.W. of Germany between the Weser, the Rhine, and the Ems; while the name *Ostphalia* was applied to the tract between the Weser and the Elbe. Both districts were included under the name Sauerland, and formed a part of the great duchy of Sachsen, of which a portion belonged to the archbishops of Köln. This formed the duchy of W., which lasted from 1179 to 1802, when the duchy was joined to Hessen-Darmstadt, and in 1815 to Prussia, forming, with the addition of several small principalities, the present province of W.

Westpha'lia, a kingdom formed by Napoleon in 1807 for his brother Jerome, consisting of the territories of Braunschweig-Wolfenbüttel and Hessen-Kassel, the Prussian provinces of Magdeburg and the Old Mark on the left bank of the Elbe, with parts of the present provinces of W. and of Hannover. Its area was 14,500 sq. miles, and its pop. 1,947,000. After the disaster at Leipzig in 1813, Jerome was compelled to fly from his kingdom, and by the Treaty of Vienna his dominions were given back to the different possessors from whom they had been torn. See *Le Royaume de Westphalie; Jérôme Buonaparte, Sa Cour ses Favoris et ses Ministres. Par un Témoin Oculaire* (Par. 1820).

Westpha'lia, Treaty of. See THIRTY YEARS' WAR.

West Point, a military post, and the seat of the United States Military Academy, on the W. bank of the Hudson, between the towns of Highlands and Cornwall, 52 miles N. of New York. In the midst of the romantic 'Highlands of the Hudson,' the Academy stands on a plateau 160 feet above the river, flanked towards the river by rocky heights. In the angle of the river opposite the Point is Constitution Island, a rocky mass rising to a height of 130 feet. The Academy was founded in 1802 for 56 cadet artillerists and engineers, a number increased to 250 in 1812. It is governed by 41 professors and teachers, under a board of visitors. Since 1861 the course of study has been fixed at four years, and while largely mathematical and professional, it includes among other subjects French and Spanish, drawing, chemistry, geology and mineralogy, mechanics, optics, astronomy, and military and international law. In the nomination of cadets, sons of soldiers who have been killed in battle have a preference, and each member of Congress has the right to nominate 1 cadet from his district, while the President can nominate 10. From 1802 to 1864 the number of graduates was 2592, and the total sum expended on the Academy amounted to $7,133,235. Near the Academy is Camp Town, comprising soldiers' barracks, storehouses, &c. In the Revolution War the British strove to gain control of the Hudson, which formed an important line of communication from New York to Canada. The Americans strongly fortified the Highlands, through which the river flows for several miles, and the centre of their position was W. P. The British took Forts Montgomery and Clinton in 1777, but abandoned them on the surrender of Burgoyne's army. The forts were reconstructed and augmented by Radière and the Polish hero, Kosciusko, some $3,000,000 being expended on them in two years. Washington took up his headquarters here in 1779, and in the following year Arnold received the command, and made the treasonable attempt to surrender his charge, which was foiled by the capture of Major André (q. v.). Fort Clinton has been partly restored, but the others are in ruins. See Boynton's *History of W. P.* (New York 1863).

West'port, a seaport town of county Mayo, Ireland, on Clew Bay, 11 miles W.S.W. of Castlebar by rail. It was planned and largely built by the Marquis of Sligo, and has Anglican, Roman-Catholic, Presbyterian, and Methodist churches. It has also a court-house and a convent. The linen trade, once important, is now nearly extinct, but a large export trade in provisions, &c., is carried on. In 1878, 139 ships of 19,924 tons entered, and 147 of 19,863 tons cleared this port; and 605 fishing-boats, employing upwards of 3000 men, were registered here. W. is now a favourite sea-bathing resort. Pop. (1871) 4417.

West Prussia. See PRUSSIA.

West Troy, a suburb of the city of Troy (q. v.), U.S., lies on the right bank of the Hudson, which is here crossed by an iron bridge, and at the entrance of the Erie and Champlain Canals. The town is well laid out on a gentle slope, and contains several fine buildings, including a public market erected in 1876. It has not yet obtained a charter, though much the largest village in New York State. The trade is chiefly in lumber, though some cloth and hardware goods are also manufactured. Adjoining W. T. is the Waterolict United States Arsenal. Pop. (1870) 10,693.

Wet'stein, Johann Jakob, born at Basel, 5th March 1693, after studying theology was for some time chaplain to a

Swiss regiment in the service of Holland, and in 1717 became dean of his native town. Deprived of his post in 1730 on a charge of Socinianism, he three years later accepted a call to the chair of ecclesiastical history at Amsterdam, where he died 23d March 1754. His critical edition of the New Testament (2 vols. Leyd. 1751–52), for which W. collated many important MSS., is furnished with exegetical notes from Jewish, Greek, and Latin writers, and still retains its value. The *Prolegomena*, previously published in a separate form (Amst. 1730), were re-edited by Semler (Halle 1764).

Wett'e. See DE WETTE.

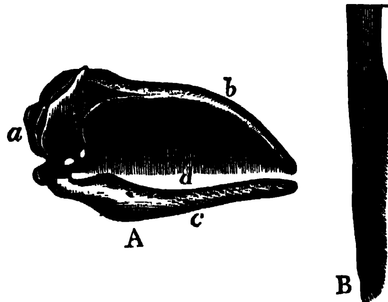
Wett'er, Lake, in S. Sweden, surrounded by the läns of Östergötland, Nerike, Vestergötland, and Smaland. It is 125 miles long, 31 miles broad, and 410 feet deep, and lies on a shelf of the Swedish mountain system, so that it is fed by no considerable stream. It is conjectured that its cold, clear, blue waters are drawn from hidden springs. It is remarkable for its *mirages*, its periodic rise and fall, and the sudden commotions of its surface that often take place amid a general calm. Through the middle of the lake runs lengthwise a shallow, from which islands rise here and there. Lake W. has its outlet near the middle of its E. coast by the Motala, and is connected with the Skagerak and with the Baltic by the Göta Canal.

Wett'erhorn ('peak of tempests'), one of the most striking peaks of the Bernese Oberland, has three summits—the W., called by the natives Hasli-Jungfrau, 12,147 feet high; the middle, known as the Mittelhorn, 12,165 feet; and the E., the Rosenhorn, 12,110 feet. These were ascended first in 1844 and frequently since, the ascent being made from Grindelwald, and the previous night spent at a club-hut built among the rocks at the foot of the main peak. The contrast between the bright fresh pastures and the black precipices and dazzling snow-ridges of the W. is particularly striking, making the valley of the Reichenbach a favourite resort of artists.

Wetz'lar, a town of Rhenish Prussia, on the Lahn, 95 miles S.E. of Köln by rail. It has a cathedral, built at intervals during the 13th, 14th, and 15th centuries, and still unfinished. Protestants worship in the choir, Catholics in the nave. There are also a gymnasium and a synagogue, and glove-factories, spinning, iron-works, phosphorus-works, &c. Pop. (1875) 6837. W. is a scene in Goethe's *Werther*. It first appears in history during the 12th c. The Diet of Spires met here from 1689 to 1808. See Wigand's *W.* (Wetz. 1862).

Wex'ford, a maritime county in the province of Leinster, Ireland, is bounded N. by Wicklow, E. by St. George's Channel, S. by the Atlantic, and W. by Waterford, Kilkenny, and Carlow. Area, 572,920 acres; pop. (1851) 180,159, (1871) 132,666, a decrease due to the emigration of 54,021 persons during 1851–77. With a dangerous coast-line, W. is tolerably level, its central district being only broken by such isolated summits as Carrickbyrne (767 feet), but on the northern frontier are Blackstairs Mountain (2409 feet) and the Mount Leinster Ridge (2610 feet). Bounded W. by the Barrow, it is traversed by the Slaney and its affluent the Bann, but the entire water area of the county is only 3668 acres. Clay-slate is the prevailing formation, and the climate is mild, the rainfall of 1877 varying at different points from 42·39 to 65·47. Of 216,590 acres under crops in 1878 (247,510 in 1853), 7816 were in wheat, 44,004 in oats, 52,081 in barley, bere, and rye, 22,853 in potatoes, 18,210 in turnips, and 61,696 in meadow and clover, while woods and plantations covered 9765 acres in 1877. The live-stock included 28,725 horses and mules, 8156 asses, 115,921 cattle, 159,850 sheep, and 73,605 pigs in 1878, when the rateable valuation was £375,259. The population is mainly agricultural and Catholic, there being only 12,310 Protestants in 1871; and of the total, 31·7 were illiterate, though W. had 264 schools. Wexford, New Ross, Enniscorthy, and Gorey are the chief towns of the county, which returns two members to Parliament. The territory of Ptolemy's *Menapii*, W. was first harried then colonised by Danes, formed the starting-point of the English conquest (1169), was terribly subjugated by Cromwell (1649), and became the chief seat of the Irish rebellion of 1798, 15,000 United Irishmen mustering in the camp on Vinegar Hill, near Enniscorthy. Antiquities abound throughout the county, from Celtic *raths* to ruined castles and monasteries of mediæval times.

Wex'ford, the capital of the county of the same name, and a parliamentary borough, 74 miles S. of Dublin by rail, at the mouth of the river Slaney, which here expands to form a harbour 6 miles long. It contains three Roman Catholic churches, two Episcopal, one of which, St. Selsker, dates from about 1200, and meeting-houses belonging to minor sects, St. Peter's College, a preparatory school for Maynooth, a diocesan Protestant school, and various others. The trade is chiefly retail, but corn, poultry, and oysters are shipped to Liverpool, with which there is regular steamboat communication. The harbour is finely situated, but a bar at its mouth prevents the entrance of any but small vessels. In 1878 there entered 852 vessels of 80,892 tons, and cleared 812 of 79,110 tons, the imports amounting (1877) to £21,654, and the customs to £6441. The borough returns one member to Parliament, and supports four newspapers. Pop. (1871) 12,077, of whom 11,196 were Roman Catholics.



Wey'er, Sylvain van de, a Belgian statesman, born in 1802 at Louvain, studied law there, and subsequently practised at the bar in Brussels till appointed city librarian, keeper of the Burgundian archives, and professor at the museum. These appointments he lost in consequence of his becoming leader of the opposition and co-editor of the *Courrier des Pays-Bas*. After the Revolution of 1830 he was a member of the Committee of Public Safety, and of the Provisional Government, and in the National Congress was a zealous advocate of the exclusion of the House of Orange. In November 1830 he was commissioned to confer with the English cabinet, and on his return he became President of the Diplomatic Committee and Minister of Foreign Affairs (February 26, 1831). On the accession of Prince Leopold, W. was appointed ambassador to England. Recalled in 1845 to form a new cabinet, he failed as Minister of the Interior to reconcile the Liberal and Catholic parties, and in 1846 returned to his former post in London, which he held till his resignation in 1867. He died in London, May 23, 1874. His literary works are published under the title *Choix d'Opuscules Philosophiques* (5 vols. Lond. 1863 *et seq.*). See Juste, *Les Fondateurs de la Monarchie Belge* (vols. x. and xi., Brus. 1871).

Wey'mouth, a township of Massachusetts, U.S., 11 miles S. of Boston by rail, has 6 printing-offices, a sanatorium, 1 newspaper, and manufactures of boots, iron, drugs, &c. Pop. (1870) 9010. Founded in 1626, W. is the second oldest settlement in the State.

Wey'mouth and Mel'combe Re'gis, a seaport and watering-place of Dorsetshire, England, 8 miles S. of Dorchester by rail, stands on a curving bay, which is bounded W. by the Isle of Portland (q. v.), and E. by St. Alban's Head. The Wey, after widening into a 'back-water,' here enters the sea, and Weymouth, an old-fashioned fishing-town, stands on its right, on its left bank Melcombe Regis, with handsome terraces and a fine esplanade, at the W. end of which is a pile pier erected in 1859 at a cost of £12,000. There are four churches, Holy Trinity (1836), St. Mary's, St. John's (1854–68), and Christ Church (1874), and other buildings are the guildhall, market-house, assembly-rooms, baths, masonic hall (1816), middle-school (1860), collegiate school recently built, hospital, and dispensary opened in May 1872, eye infirmary which was opened for the reception of patients in May 1872, and the sanatorium (1862). The bay is commanded by the Nothe Fort, W. of the harbour. This fort has fifteen of the heaviest guns in use, bomb-proof magazines for shot and shell, and barrack-rooms for a garrison of 800 men. In 1878 there entered 925 vessels of 107,921 tons, and cleared 942 of 102,578 tons; and on 31st December 41 vessels of 4074 tons upon the register of the port, including a line of mail steamers to the Channel Islands. In the same year the Great Western Railway opened a traffic between this port and Cherbourg, and steamers ply to and fro daily, Sundays excepted, to Portland. In 1877 the exports (Portland stone and agricultural produce) amounted to £158,277; the imports (wine, spirits, coal, and timber) to £126,246; and the customs to £10,195. To summer visitors, however, Weymouth mainly owes its prosperity, which dates from the visits of the royal family towards the close of last century. It publishes three weekly newspapers (two of which are printed at Dorchester), and returns two members to Parliament. Pop. (1821) 6622, (1871) 13,259.

Whale, the name applied to the larger Mammals belonging to the order *Cetacea* (q. v.). The adaptation to an aquatic

existence of necessity involves a departure to some extent from the ordinary Mammalian type of structure, and in the true whales, as typically exemplifying this group, the chief points of difference may be conveniently studied. Externally, the immense bulk of the *Cetacea* attracts attention, as also does the essentially fish-like shape of the body. The regions of the body are indistinctly marked, no true neck being discernible, and the enormous head being apparently united directly to the trunk. Posteriorly, a transverse or horizontally-placed caudal-fin terminates the body. This fin is merely an expansion of the integument, strengthened by a cartilaginous framework. A median 'dorsal-fin' is also sometimes found. Anterior limbs exist in the form of swimming-paddles, but posterior limbs are undeveloped throughout the order.

CETACEA.

A. Skull of Whalebone Whale (*Balæna mysticetus*). *a*, Cranial portion of skull; *b*, upper jaw; *c*, lower jaw; *d*, baleen.
B. Single plate of baleen, showing the fibrous edge by which the plates are united together.

The facial bones are large and extended as compared with the cranial portion of the skull (Fig. A, *a*); and in the Whalebone Whales (*Balænidæ*) the upper maxillary or jaw bones (*b*) bear deep ridges, in which the plates of 'whalebone' or 'baleen' (*d*) are inserted. These plates, which are flattened, and of elongated shape, are so attached to the palate that the long axis of each depends into the cavity of the mouth; the entire series of plates thus forming as it were a double median fringe to the upper jaw (*b*). The outer or free edge of each plate is fringed in turn by a fibrous arrangement of the whalebone (Fig. B), binding the entire structure more closely together, and so tending to render it more effective in its purpose, which is undoubtedly that of acting as a 'sieve' or 'strainer;' preventing substances of large bulk from passing into the contracted œsophagus of the animal, and at the same time serving to retain and entangle the minute organisms upon which these creatures principally subsist. The food of the W., therefore, consists principally of *Pteropodous* Mollusca, which exist in countless shoals in the Arctic Seas; and certain members of which, from the foregoing circumstance, have received the collective title of 'whale's food.'

The chief points of interest in the skeleton of the *Cetacea* are comprised under the consideration of the modifications of the vertebral column and pelvic extremities. The cervical segments of the spine, in the present instance, are generally anchylosed together, whilst the dorso-lumbar vertebræ are exceedingly mobile, to admit of the extensive movements of the tail in locomotion. There is no true sacrum, one of the vertebral segments being by some authorities regarded as representing this bone. The skeleton of the anterior members is entirely homologous with that of other and higher *Mammalia;* the clavicles, however, being wanting throughout the order. The bones of the forearm are more or less firmly united to each other, and the entire limb is contained and hidden within the thick integument or skin, and is thus converted into an effective swimming-paddle. Posterior limbs are wanting in Cetaceans, only a few species (*e.g.*, the whalebone whales) having a rudimentary femur, while the haunch-bones or *pelvis* are represented by two small bones imbedded among the muscles of the abdomen. The posterior ribs are not attached to the breast-bones, but simply spring from the spine above. The teeth of whales are as a rule conical in shape, and are present in all whales save the *Balænidæ* or whalebone W., although teeth are represented in the fœtal state of the animal. The stomach of whales appears to tend towards a compound type of structure, and in some respects resembles that of the *Ruminantia* (q. v.). The breathing apparatus presents us with several structural features worthy of notice. The nostrils are known as *blowholes* and *spiracles*, and are placed in *Balænidæ* on the top of the head. They play an important part in the respiratory process, and the soft palate embraces the conical aperture of the windpipe so as to form a continuous air-passage from the posterior nostrils to the larynx, the food passing on each side of this passage.

Respiration is thus performed independently of the peculiar mode in which the process of nutrition is carried on; the animals rising at stated intervals to the surface of the water to inhale a fresh supply of air. At such times the inspired air is ejected from the 'blow-holes.' This so-called 'spouting' is not caused (as was once supposed) by the ejection of the water taken into the mouth in the act of nutrition, but by the heated air of respiration, condensed on exposure to the cold of the atmosphere, together with such superfluous water as may have gained admittance to the nostrils from without, or such superjacent water as may be driven up in the form of spray by the violent nature of the respiratory act.

An external ear is absent, but from the relation of the internal ear to the nasal passages, it is highly probable that the latter apertures subserve, in some measure at least, the purpose of a medium for the collection and transmission of sounds to the auditory centres.

The *Cetacea* in their reproduction exemplify all the characters of the higher *Mammalia;* these creatures suckling their young for a considerable period after birth, and exhibiting for their offspring the greatest care and affection.

As regards classification, whales are divided into three families. (1) The *Balænidæ* or Whalebone Whales, distinguished by the absence of teeth, by the presence of *baleen* or *whalebone*, and by the nostrils being placed on the top of the head. Of this family the Right or Greenland W. (*Balæna mysticetus*) is the typical representative, and constitutes the chief object of pursuit for the sake of the *blubber* and *whalebone*. The former substance forms a thick coating of fat serving at once to preserve an equable temperature, and to assist in reducing the specific gravity of the animal. The Right W. and the Southern W. (*B. Australis*) form the section of this family known as the 'Smooth' Whales, and which are distinguished by the absence of a dorsal fin. In the 'Furrowed' Whales, forming the second section of this family, there is a dorsal fin, and the skin is rough or furrowed, the group being sometimes known as the 'Finner' Whales. Two genera appear to be included in this section, these being known respectively as *Megaptera* and *Balænoptera*. The familiar name of Rorqual is applied to a species of this latter genus (*Balænoptera Boöps*). (2) The *Physeteridæ* or Sperm Whales, sometimes known as the *Catodontidæ*, are distinguished from the preceding family by having a large number of conical teeth in the lower jaw, those of the upper jaw being rudimentary; by the absence of 'baleen plates,' and by the great relative size of the head, at the anterior extremity of which the united nostrils are situated; this last character being essentially different from the disposition of these apertures in the *Balænidæ*. The Spermaceti W. or cachalot (*Physeter macrocephalus*), the most familiar example of the group, is hunted for the sake of the oil, spermaceti, and ambergris. The substance known as spermaceti is a peculiar fat, found principally in the cranial cavities of the animal, and much esteemed in the manufacture of unguents, and for other purposes of the pharmaceutist. The ambergris, which is found in the digestive tract, obtains its commercial repute as an ingredient in perfumes. The sperm whales inhabit the Southern Seas, and are gregarious. They swim in companies technically named 'schools,' numbering from 20 to 50 individuals. (3) The *Delphinidæ* or dolphins, including the Dolphin (q. v.), Grampus (q. v.), Porpoise (q. v.), Narwhal (q. v.). &c.

Whale'bone, the name given to the long, thin, parallel laminæ, horny in nature and bluish-black in colour, which are developed in the mouths of the family of whales called *Balænidæ*. The substance has nothing of the nature of *bone*, and is more appropriately called *baleen*. W. is valued for its strength, flexibility, compactness, and lightness. It is cleansed and softened by immersion in boiling water, and thereafter cut up into strips for making ribs of umbrellas and parasols, supports for stays and other articles of female apparel.

Softened in a steam bath, it may be moulded like horn into walking-stick and whip handles, &c. The bristles which fringe the blades are employed in brush-making, and W. shavings form a useful stuffing material. The market value of W. ranges from £200 to £400 per ton. The imports of W. or *whalefins* into the United Kingdom in 1877 amounted to 1969 cwts., valued at £82,987. The tusk of the walrus was formerly designated W., hence mediæval authors always speak of it as *white* in colour.

Whale' Fish'ery. The species of the *Cetacea* or Whale family hunted for the sake of the commercial products they afford, are the Right or Greenland whale, the Sperm whale, and other species of true Cetaceans, whilst the porpoises and their neighbours are also hunted for the sake of their oil and skin. The whaling fleet consists of a specially-organised class of vessels, sailing in Britain chiefly from Hull, Peterhead, and Dundee. New Bedford and Nantucket in the United States also send a fleet to this fishery, and the Norwegians occasionally fit out vessels for it. The ordinary whaling-vessels are now screw steamships, strongly built in view of the ice-sheets and the disastrous effects of collisions with ice-floes. The crew number from 30 to 40 men. The *harpoon* with which the whale is struck is an iron rod attaining a length of 5 feet, and possessing an arrow-shaped head. The whale, on being struck with the harpoon, dives and remains under water for about twenty minutes, the line to which the harpoon is attached being duly paid out by the harpooner. On rising the W. may be again struck, and it is subsequently pierced in a vital part with a lance or spear. The body of the animal is then made fast to the ship, and the work of *flensing* or that of stripping off the blubber begins. Thereafter the blubber is melted down into oil, and that fluid is duly stored. One ton of blubber may yield 200 gallons of oil. The whalebone is also taken out of the mouth of the animal, and is simply dried and packed. Methods of killing whales by employing harpoons charged with poison have been employed in the W. F., but the whalers appear to have some objection to use this means, though it has the advantage of killing the animal at once, and so preventing risk and obviating danger. As early as the 9th c. the Norwegians prosecuted the W. F. in Greenland; the English and Dutch first entering upon it in the 16th c. In 1680 Holland employed 260 vessels and about 14,000 men in the W. F. In 1815 England employed only 164 ships; but of late years, owing to the scarcity of whales, the W. F. has decreased rapidly, and it may be feared also permanently. America at present appears to lead the van in the matter of fishing enterprise: about 200,000 casks of oil and 150,000 casks of spermaceti being annually obtained by the American fleet.

Whales, in English law, are crown property, provided they are caught within 3 miles of the coast, or are stranded. Otherwise the animal is the property of the person who captures it; and by common consent a whale is the property of the harpooner only so long as the harpoon remains attached by line to the boat.

Whale Louse (*Cyamus ceti*), a species of *Crustacea* (q. v.) belonging to the order *Læmodipoda*, in which the first segment of the chest is united with the head, thus placing the first pair of limbs beneath the throat. In the W. L. the body is short and broad, and has seven pairs of legs, some of the feet being strongly hooked. The animal is found adhering sometimes in immense numbers to the whales, and it is said to destroy the outer cuticle or epidermis. The legs constitute the adhesive organs, and the mouth is provided with a suctorial proboscis.

Whar'ton, Philip Wharton, Duke of, son of the Whig marquis to whom is ascribed the authorship of *Lilliburlero*, was born in December 1698. Trained by his father in Whig and Presbyterian principles, he broke that father's heart by marrying at the Fleet the daughter of a Major-General Holmes (1715); next, leaving his bride, set out for Geneva with a French Huguenot for governor. Tutor and ward soon parted, the latter 'flying as from the plague' to Avignon, where the Old Pretender conferred on him the title Duke of Northumberland; and Mary of Modena lent him £2000. This squandered at Paris, he came to Ireland, and sitting a minor in the House of Lords, so ably upheld the Hanoverian government as to earn for reward a real English dukedom, 20th January 1718. His gratitude showed itself in hot resistance to the government's South Sea Bill (1721) and Bill of Pains and Penalties against Atterbury (1723), as also in his Opposition *True Briton* (74 numbers, 1723-24), started to retrieve a fortune which from £16,000 a year had dwindled to £1200 allowed by creditors' trustees. This venture failed, and in 1724 he quitted England never to return. From Vienna he wandered to Madrid, and there, letting lie unopened a Privy Council summons, he professed himself a convert to Catholicism and open adherent of the House of Stuart; there too, within a month of his first wife's death, he married an Irish maid-of-honour to the queen. At Rome the Pretender invested him with the Order of the Garter, but from Rome his excesses procured him a courteous dismissal, and 1727 found him engaging with reckless bravado in the siege of Gibraltar, thus purchasing a Spanish colonelcy by the loss at home of peerage and estates. Madness and drunkenness drove him to Paris, Orleans, and back to Spain, where a foolish quarrel embroiling him with the Madrid court, he fell into melancholy and a deep dejection. So on May 31, 1731, at a Bernardine convent in Catalonia, died he whose character Pope well sums up—'W., the scorn and wonder of our days.' The *Life and Writings of Philip, late Duke of W.* (2 vols. Lond. 1732), contains nothing beyond the *True Briton* and the eloquent speech on Atterbury's behalf, whilst in his so-called *Poetical Works* (all but a Memoir printed in 1727) some prose letters are all that can be safely attributed to his pen. Some of his effusions, however, may be found in vol. v. of Nichols' *Select Collection of Miscellaneous Poems* (8 vols. 1780-82).

Whate'ly, Richard, Archbishop of Dublin, one of the most vigorous thinkers and writers among the churchmen of the 19th c., was the son of an English clergyman, and was born at London, February 1, 1787. He studied at Oxford, became fellow of Oriel (1811), Principal of St. Albans Hall (1825), Professor of Political Economy at Oxford (1830), and Archbishop of Dublin (1831). He died at Dublin October 8, 1863. The chief writings of W. are (1), *Historical Doubts relative to Napoleon Bonaparte* (Lond. 1819), a clever parody of the Germanic sceptical criticism, which was then being applied to the Gospel narratives; (2), *Elements of Logic* (first published in 1826, a work of which numberless editions have appeared). This famous manual may be said to have revived the study of logic at Oxford. It was infinitely superior to anything that had till then appeared on the subject in the English language; and, notwithstanding the many able treatises since published, it may still be read as a clear, simple, and attractive exposition of the first principles of the science of reasoning, but it lacks thoroughness and grasp of ultimate principles. It does not show any sign of peculiar philosophical ability, and it is disfigured by errors in detail which are only excusable, when we remember that it was (in a certain sense) a work on a subject which for that generation was really a new one. (3), *Elements of Rhetoric* (1828); (4), *Thoughts on the Sabbath* (1830), a very powerfully reasoned work against the alleged binding obligation of the Mosaic Sabbath on the Christian Church; (5), *The Errors of Romanism traced to their Origin in Human Nature* (1830); (6), *Introductory Lectures on Political Economy* (1831). In addition we may mention annotated editions of parts of the writings of Archbishop King, Lord Bacon, and Paley, besides a host of sermons, charges, pamphlets, &c. W.'s position was what we should now call that of liberal orthodoxy,—orthodoxy in so far as he held firmly by the chief doctrines of the Christian faith, liberal in so far as he was disposed generally to moderate opinions. His views on the Sabbath question and his support of Jewish emancipation, and the subsidising of Maynooth, were sure marks of ecclesiastical liberalism. A great part of his writings were directed against the Tractarian party. His clear common-sense revolted strongly against their position, whilst a certain English narrowness of view, and disinclination or inaptitude to go to first principles, hindered him from perceiving the real strength of their arguments. In politics he was also a resolute liberal, and his appointment to the primacy of his Church in Ireland created much ill-will. His opinions and certain peculiarities of manner made his position for long very difficult. But he outlived dislike, and before he died there was a general recognition not only of his lucidity and strength of intellect, but of his thorough genuineness, his noble devotion to the duties of his office, and his unwearying kindness to all that sought his aid. W. was a great supporter of the Irish

National School system, and for many years was the leading member of the Board of Education. See *The Life and Correspondence of W.* by his daughter (2 vols. Lond. 1866).

Wheat (Sansk. *s'vêta*, Old Eng. *hwaete*, allied to *hwît*, 'white'—in contrast to rye, black oats, and black barley of N. Asia) is the most important of all the cereal grasses. It belongs to the genus *Triticum*, a genus in which the sessile solitary spikelets are arranged in distichous spikes, and inserted broadside to the rachis; empty glumes nearly equal; flower-glumes herbaceous, rigid; palea with ciliate nerves. There are about 25 species distributed through all temperate climates, and familiarly represented in Britain by the Couch-grass (q. v.). The W. plant is named *T. vulgare*. Its native country is not known, unless the supposition of some botanists is correct, that it has been produced by long-continued cultivation from *Œgilops ovata*, in which case it is a common plant of the Mediterranean region and neighbouring eastern countries. W. has been grown as a food-crop from the earliest historic ages, and is at the present time extensively cultivated by all civilised and semi-civilised people of temperate countries. It is grown up to 12,000 feet on the southern slopes of the Himalaya. An examination of bricks of Egyptian pyramids shows the straw and grain of W. similar to that found in Swiss lake-dwellings (*T. vulgare antiquorum* of Heer). Metzger enumerates as distinct kinds of cultivated W.:—1. *T. vulgare*, which includes numerous varieties. It comprises also the best Italian sorts for plaiting straw-bonnets and straw-hats, for which only the upper part of the stem is used, collected before the ripening of the grain, and bleached through exposure to the sun while kept moistened. 2. *T. turgidum*, comprising some varieties of White and Red W., also the Clock W. and the Revet W. 3. *T. durum*, which contains some sorts of the Bearded W. 4. *T. Polonicum*, the Polish W., some kind of which is well adapted for peeled W. 5. *T. spelta*, the Spelt corn or Dinkel W., a kind not readily subject to disease, succeeding on soil of very limited fertility, not easily attacked by birds, furnishing an excellent flour for cakes, also yielding a superior grain for peeled W. For preparing the latter it is necessary to collect the spikes while yet somewhat green, and to dry them in baking-houses. 6. *T. dicoccum*, the Emmer W. Its varieties are content with and prolific on poor soil, produce excellent starch, are most hardy in frost, and not subject to diseases. To this belongs the Arras W. of Abyssinia, where more peculiar sorts of W. are grown than in any other country. 7. *T. monococcum*, or St. Peter's corn. Is hardier than most of the other kinds, exists in the poorest soils, but produces grains less adapted for flour than for peeled W. For convenience the above may be embraced under three primary varieties of one species. 1. Var. *muticum* (*T. hybernum*, L.), the winter W. or Unbearded W.; 2. var. *aristatum* (*T. æstivum*, L.), the summer W. or Bearded W.; 3. var. *adhærens* (*T. Spelta*, L.), W. with fragile axis and adherent grain. The names red and white W. are applied according to the colour of the grain; the former are generally more hardy than the latter, but of inferior quality, and the yield is less. Winter W. is sown in autumn; summer W. in spring. The composition of W. grain shows some variations, but the following analysis may be taken as showing the proportions of the main constituents in a good sample of white English W.:—Water, 14·5; albuminoids, chiefly fibrin, 11; starch, with trace of dextrin, 69; fat, 1·2; cellulose and lignose, 2·6; mineral matter or ash, 1·7 = 100 (*Church*). These constituents are so proportioned as to render W. well fitted for the general sustenance of man, both as regards its flesh-forming and force-producing character, and it is the cheapest article of food that we possess. It is readily made into a light and spongy Bread (q. v.). Macaroni, vermicelli, and similar preparations are made from highly nitrogenous wheats. The soil best adapted to the growth of W. is a deep loam inclined to clay, with a dry subsoil. The average yield of an acre of land should be about 30 bushels (760 lbs.) of grain. A plump, rounded, white, smooth grain, without wrinkles, gives the heaviest weight per bushel. W. grain varies in specific gravity between 1·29 and 1·41, the harder samples being the denser. The proportion of grain to straw is greatest in dry years—the average is about 4 to 10. In the British Isles each person in the community is calculated to consume a little above five bushels of W. annually. The home production only supplies only about two-fifths of the requirements, all the large W.-growing countries of the world contributing the remainder. Prior to 1856 (at which date a million more acres were under W. in Britain than at the present time) the foreign imports had not exceeded 4½ million quarters; during the last five years they have averaged nearly 12½ million quarters. The yearly foreign corn trade of the country involves the movement of 6 million tons, worth more than £50,000,000 sterling. See CORN LAW.

The principal vegetable diseases to which W. is liable are of fungoid nature, and have been mentioned in articles BUNT, MILDEW, RUST, and SMUT. For those arising from the attacks of insects, see CORN MOTH, EAR COCKLES, HESSIAN FLY, WHEAT FLY, and WIREWORM.

Wheat'ear (*Saxicola œnanthe*), or **Fall'ow Chat**, an Insessorial bird belonging to the *Sylviadæ* or Warblers, and inhabiting Britain in summer. The average length is 6 inches. The male is of a light grey colour above, the wing-quills and coverts being black. The breast is buff tinged with orange, and brown tints also occur on the under parts, which are mostly white. The W. is trapped in large quantities for the table, the flesh being esteemed a delicacy when the bird is fat and well nourished. The eggs are of pale-blue colour, and number from 4 to 6. The nest is cunningly concealed in the crannies of rocks and like situations. A favourite mode of catching the W. is by means of horse-hair nooses concealed beneath a sloping piece of turf, under which the bird runs when alarmed.

Wheat Fly, the name applied to such species of insects as the *Cecidomyia tritici*, or the wheat midge, the larvæ of which feed on the wheat when in the ear and completely destroy the grain. The female W. F. lays its eggs when the wheat is in flower, and the maggots are fully developed at the end of July. The W. F. is allied to *C. destructer*, the Hessian Fly, also named the 'Wheat Midge.' The former species has transparent wings, while those of the Hessian Fly are black.

Wheat Moth, a name applied to the *Tinea granella*, a species of *Moth* (q. v.) representing the family *Tineidæ*, and which lays its eggs in wheat grains. It is allied to the Clothes' Moth (q. v.).

Wheat'on, Henry, an eminent American jurist and publicist, was born at Providence, Rhode Island, November 27, 1785, graduated at Brown University in 1802, was admitted to the bar, and spent the next two years in Paris and London. On his return he settled in New York in the practice of his profession, in 1812 became editor of the *National Advocate*, and in 1815 a Justice in the Marine Court, publishing in the same year a valuable *Digest of the Law of Marine Captures and Prizes*. From 1816 to 1827 he filled the place of reporter of the proceedings of the Supreme Court of the United States, and his invaluable *Reports of Cases Argued and Determined in the Supreme Court of the United States*, in 12 vols., have been termed 'the Golden Book of American Law.' In 1827 he was appointed by President Adams First Chargé-d'Affaires to the Court of Denmark, in 1834 he was transferred to the Court of Prussia, and in 1837 appointed Minister Plenipotentiary to the King. Recalled by President Polk in 1846, he had scarcely accepted the Chair of International Law in Harvard University, when he died at Dorchester, March 11, 1848. W.'s other works were, *The Elements of International Law* (1836), *Histoire du Progrès du Droit des Gens en Europe depuis la Paix de Westphalie jusqu'au Congrès de Vienne* (Leip. 1841), a prize essay of the French Institute, afterwards remodelled, enlarged, and published in English under the title, *History of the Law of Nations in Europe and America, from the Earliest Times to the Treaty of Washington* (New York 1845).

Wheat'stone, Sir Charles, F.R.S., D.C.L., LL.D., a celebrated electrician and physicist, was born in February 1802, at Gloucester, where his father was a music-seller. He was brought up to the trade of a musical instrument maker, and, soon after beginning business in London in 1823, he displayed a singular aptitude for experimental research in his *New Experiments on Sound*, which appeared the same year in Thomson's *Annals of Philosophy*. In 1832 he communicated to the Royal Society a paper *On the Acoustic Figures of Vibrating Surfaces*, and two years later was appointed professor of natural philosophy at King's College, London. Here he executed his researches on the velocity of electric transmission by means of

revolving mirrors—a method of experiment which has been used by others with great success in other departments of physics—for example, by Fizeau in his determination of the velocity of light. He early turned his attention to spectrum indications, and pointed out the possibility of distinguishing metals according to the spectrum character of the electric spark passed between them. In the measurement of electrical resistance, his name is handed down to posterity as the inventor of *W.'s Bridge* (see ELECTRICITY). Other important inventions are his 'polar clock,' for ascertaining the time by the position of the plane of polarisation of the light of the polar sky; the catoptric Stereoscope (q. v.); and the Kaleidoscope (q. v.). His greatest fame, however, rests upon his practical applications of electricity, and especially upon the position he holds as one of the founders of the electric telegraph (see TELEGRAPH). He was knighted in 1868, elected a foreign member of the Academy of Sciences in Paris in 1873, and one of the eight foreign associates of the same in 1875, and had besides upwards of thirty foreign distinctions. He died at Paris, October 19, 1875. Though he never published, save in scientific journals and transactions, he has left behind him a lasting memorial in the discoveries, applications, and inventions which have so changed the aspect of the world's civilisation within the last half-century. The council of King's College, London, have decided (1879) to give the name of the 'W. Laboratory' to their physical laboratory, where W. made his early researches, and to which he bequeathed his valuable scientific apparatus.

Wheel, Breaking on the, a mode of inflicting death, formerly in use in various countries of Europe, in which the victim was placed upon a wheel, with his arms and legs extended along its spokes, and the wheel being rapidly turned round, his limbs were broken by repeated blows from an iron bar. Sometimes two or three blows—*coups-de-grâce*—were given to shorten the sufferings of the victim. This barbarous punishment, now happily a thing of the past, still lives in the word *roué* ('a rake'), the past participle of the French verb *rouer*, 'to break upon the wheel.'

Wheele'ra, or **By'ra,** is a genus of *Leguminosæ*, consisting of three species. *B. ebenus* (the Jamaica or W. Indian ebony-tree) is a small tree, the wood of which is very hard and ponderous, sinking in water. It takes a fine polish, and is used for making various small-wares, but has no affinity with the true ebony. It is also used by tanners and dyers under the name of green ebony.

Wheel and Axle, in mechanics, is a modification of the Lever (q. v.), much used in wheel-work and other combinations of machinery. It consists essentially of two different-sized wheels, which can rotate as a rigid system about the same axis. A force applied to the circumference of the smaller wheel or *axle* is balanced by a force applied to the circumference of the larger *wheel*, which is less than the former force in the ratio of the radius of the axle to the radius of the wheel. The system, indeed, acts as a lever, whose arms are the radii and whose fulcrum is the common centre, and supplies an efficient means for overcoming a great resistance by a comparatively small force acting tangentially at the circumference of the wheel. The windlass is a familiar example of a simple W. and A., and the principle is again met with in the Flywheel (q. v.).

Wheel'ing, capital of W. Virginia, U.S., 92 miles S.W. of Pittsburg by rail. It has over 20 churches, a library, theatre, 3 daily and 5 weekly newspapers. The surrounding country is rich in bituminous coal, and has 5 blast furnaces, 7 nail factories, numerous foundries and other ironworks. A great railway centre, W. also carries on an important trade by river; and in 1875, 73 steamers and 128 barges (aggregate tonnage, 9891 tons) were registered here. Pop. (1870) 19,280; estimated in 1876 at 30,000. Settled in 1774 and incorporated in 1806, it was made the capital of W. Virginia in 1863.

Wheelwork is any combination of wheels for transmitting or regulating motion. The essential element in all such combinations is of course the wheel, which is simply a form of lever so contrived that the power can be applied continuously and uniformly. The use of wheels to facilitate locomotion dates from a very early period in the history of civilisation, as is evidenced by the frequent references to them in the oldest known literature, the Indian *Vedas*; and the carriage or chariot was probably a gradual development from the cylindrical tree-trunk placed as a roller beneath a load. In the action of a roller we recognise a particular case of what is known in the kinematics of machinery as motion by *rolling contact*, the general principle of which is that the points of contact of the surfaces of the two moving pieces are at the instant of contact moving in the same direction with the same velocities. Hence the linear velocity of a smooth rack in rolling contact with a roller rotating round a fixed axis is equal to the product of the angular velocity of the roller into the distance of the contact-points from the centre of rotation; and this is always the measure of the relative velocity of the rack and roller, whatever the apparent velocity of either may be; whether, as in a carriage-wheel, the rack is fixed and the roller moves, or, as in translation by means of movable rollers, both rack and roller move. In the latter case there are really two smooth racks, the road and the object moved, and the object evidently progresses at twice the rate of the intermediate roller. An important case of rolling contact is that of two wheels or rotating pieces. If their axes are fixed, the kinematical condition of rolling contact between these wheels requires that their angular velocities are inversely as their radii. The ratio between these angular velocities is called the *velocity ratio*, and indicates the speed with which the axis of the one wheel should rotate for a given speed of the axis of the other. In circular cylindrical wheels, by which motion is transmitted between parallel shafts, the wheels rotate in the same plane, and the velocity ratio is constant. If both rolling surfaces are convex, the case is one of *outside gearing*, and the wheels rotate in opposite directions; if one surface is concave, the case is one of *inside gearing*, the one wheel rolling inside the other, and both rotating in the same direction. To transmit a constant velocity-ratio between shafts which intersect, the rolling surfaces must be portions of right cones with their vertices at the point of intersection. If the shafts are not parallel and do not intersect, the surfaces must be frustra of hyperboloids of revolution, which touch along a common generating line. With smooth rollers, however, it is practically difficult to transmit rapid motions on account of the slipping of the surfaces in contact. The friction of contact may be increased by cutting circumferential wedge-shaped grooves in the rollers, so adjusted that the projections on the one fit into the recesses of the other, as in what is known as *frictional gearing*. Not even by this means, however, is slipping altogether prevented. The most usual method of communicating motion between two wheels or between a wheel and a rack, so as to preserve an absolutely constant velocity ratio, is by means of *teeth*. These consist of a series of ridges alternating with hollows or spaces, set nearly parallel to the lines of contact of the imaginary toothless surfaces which would transmit the same velocity ratio as the toothed wheels do. These imaginary rolling surfaces are called the *pitch-surfaces*; and it is with reference to them that a wheel is first designed and the form of the teeth deduced. According to the form of the pitch-surfaces, wheels are classified as *spur-wheels*, with cylindrical pitch-surfaces; *bevel-wheels*, with conical pitch-surfaces; and *skew-bevel wheels*, with hyperboloidal pitch-surfaces. The *pitch-line* is the section of the pitch-surface with a surface perpendicular to it and the axis of rotation. This orthogonal surface is a plane perpendicular to the axis in spur wheels, a sphere with centre at the apex of the conical pitch-surfaces in bevel wheels, and an ellipsoid of revolution confocal with the hyperboloidal pitch-surfaces in skew-bevel wheels. In toothed wheels the *pitch* is the distance, measured along the pitch-line, from the front of one tooth to the front of the next. For wheels which rotate continuously, the pitch must be an aliquot part of the circumference; and in order that a pair of wheels may work together the pitch must be the same in each. The velocity-ratio of such wheels is then given as the ratio of the number of teeth in the one to the number of teeth in the other. The dynamics of toothed gearing is that the teeth of the one wheel called the *driver* push against those of the other or *follower*, and during the action sliding takes place between the pairs of teeth in contact in a direction across their lines of contact. Here is what is called *sliding contact*, the general principle of which is that the components, along the common normal to the surfaces in sliding contact of the velocities of the points of contact are equal; and for theoretically perfect gearing this normal at any instant should

pass through the line of contact of the imaginary pitch-surfaces of the wheels. A glance at the existing conditions of wheels in toothed gearing will show that the relative sliding motion of any two teeth in contact is such that the roots of the teeth approach with constantly-diminishing velocity, until for an instant they are stationary relatively to each, after which they recede with constantly-increasing velocity until they are beyond each other's influence. At this instant, when the relative sliding motion is changed from *approach* to *recess*, the point of contact of the teeth should be coincident with the pitch-point or point of contact of the pitch-lines. Hence the path of the point of contact of the teeth passes through the pitch-point, and is divided by it into two portions, known as the path of approach and the path of recess; and in general the lengths of these paths must be so adjusted that two pairs of teeth at least shall be in contact at any instant, though in certain cases this is not possible. Now the relative motion of any two wheels is equivalent to the rolling of the one wheel upon the other fixed, the instantaneous axis of rotation passing through the pitch-point (see ROTATION). Hence, in order that the teeth may remain continuously in contact, the form of the tooth of the fixed wheel should be the envelope of the successive positions of the tooth of the rolling wheel. Given the form of tooth of one wheel, then it is a comparatively simple geometrical problem to find the proper form of the tooth of another wheel to gear with it. Only certain forms of teeth, however, are practically realisable as wheel teeth, those forms being avoided which would make the complementary teeth entirely concave. It is impossible here to enter into a discussion of the best forms of teeth for practical ends; for an account of these, the reader is referred to the standard treatises given below.

For uniform working, it is evident that the teeth of the wheels in gearing should be equal and similar to one another; and to preserve this uniformity the more effectually, each given tooth in one wheel should work with as many different teeth in the other as possible. From this point of view, then, the numbers of teeth on the pair of wheels should be either prime to each other, or such as to have their greatest common measure as small as possible. The former condition is satisfied by a pair of wheels, the numbers of teeth on which are the numbers which express in its lowest terms the velocity-ratio to be transmitted by the gearing. Should the velocity-ratio be expressible by the quotient of two numbers, one of which at least is smaller than the minimum number of teeth realisable in practice, it becomes necessary to take equal multiples of these numbers as the numbers of teeth to be employed; and then, if the exactness of the velocity-ratio is not of paramount importance, the evil of frequent contact between the same pairs of teeth is avoided by giving an additional tooth, called a *hunting-cog*, to the larger of the two wheels. If the velocity-ratio exceeds 6, it is usually more advantageous to employ a *train of W.*, which consists of more than two axis, each having upon it two wheels, one of which acts as follower to the driving wheel on the preceding axis, and the other as driver to a wheel on the succeeding axis. The last variety of W. is that included under the name *banded* or *belted* wheels. Here rotation is transmitted from one wheel to another at a little distance from it by connecting them with an endless band or belt, tightened so as to cause sufficient friction to make the belt adhere to the surface of the wheel with which it is in contact. Necessarily, of course, there is slipping, especially at great speeds, so that the velocity-ratio transmitted cannot with certainty be calculated. In the ease and comparative silence with which they work, in the facility they offer for transmitting motion between wheels at some distance apart, and in the readiness with which by their means the motion may be reversed, banded wheels have over teethed wheels certain advantages which commend them for various purposes. For complete systematic treatment of the subject, see Rankine's *Machinery and Millwork* (3d ed. 1876), or his *Applied Mechanics* (9th ed. 1878), and Unwin's *Elements of Machine Design* (2d ed. 1878).

Whelk (*Buccinum undatum*), a species of Gasteropodous Mollusca, common around British coasts, and typically representing the family *Buccinidæ*, in which the shell has a prominent notch for the passage of the breathing-siphon, the shell itself having a large dilated body-whorl and an expanded aperture. The W. is popularly named the 'Roaring Buckie' in Scotland, from the well-known sound heard when the shell is applied to the ear. The mollusc is of carnivorous habits, and feeds on garbage and refuse, acting in this way as a sea-scavenger. It is eaten by the poorer classes in London and other large towns, but the flesh is rather tough and unpalatable. The Dog W. is the *Purpura lapillus*, a gasteropod belonging to the same family as *Buccinum*, and the name Dog W. is also given to species of the allied genus *Nassa*, in which the lip of the shell has a projection wanting in Buccinum itself.

Whew'ell, William, Rev., D.D., the Eratosthenes of his time, was the son of a Lancashire tradesman, and was born 24th May 1794. When he went up to Trinity College, Cambridge, in 1812, he is reported to have been a raw and unpolished youth; but he had already done good work at the grammar-schools of Lancaster and Haversham, and he soon showed what stuff he was made of, and became the natural associate of many of the best students in the university, Herschel, Richard Jones, Julius Charles Hare, and Hugh James Rose. In 1814 he gained the Chancellor's medal for the English prize poem, and in 1815 he took his B.A., and obtained the position of second wrangler. For the next eight years he was engaged as a private tutor, but at the same time was laying the first stones of his literary reputation. From 1828 to 1832 he held the chair of mineralogy in Cambridge, and from 1838 to 1855 he was professor of moral theology or casuistical divinity. In 1841 Sir Robert Peel appointed him Master of Trinity in room of Dr. Wordsworth, who had resigned, and in 1855 he became vice-chancellor of the university. His death, 6th March 1866, was the result of a fall from his horse. It was of Dr. W. that Sydney Smith said, 'Knowledge is his forte and omniscience is his foible,' and the epigram hits off what was the predominant characteristic of his intellect. In his college days we find him already, as he himself puts it, under the spell of the demon of universal knowledge. His friends appear to have warned him of his danger, but it was his fate, and no one can now say that the fate was an unenviable one. He was at once a proficient in mathematics and mechanics, a geologist and a mineralogist, a philosopher both in logic and morals, a political economist, a grammarian, and a student of architecture, and as Sir John Herschel said of him, a more wonderful variety and amount of knowledge in almost every department of human inquiry was perhaps never in the same interval of time accumulated by any man. Besides a number of text-books in mathematics and mechanics which helped to introduce the continental methods into England but are now superseded, W. wrote *Astronomy and Physics, considered with reference to Natural Theology, being the third Bridgewater Treatise* (Lond. 1833, new ed. 1864); *The History of the Inductive Sciences* (3 vols. 1837); *The Philosophy of the Inductive Sciences* (2 vols. 1840), which was afterwards remodelled and divided into three parts, published separately—I. *History of Scientific Ideas*, II. *Novum Organon Renovatum*, III. *The Philosophy of Discovery*; *History of Moral Philosophy in England* (1852); *On the Plurality of Worlds* (1853), in which he took the negative side; and *Lectures on Political Economy* (1863). He took part in the discussion about English hexameters, and supported the innovators by argument and example; he translated *The Platonic Dialogues for English Readers* (3 vols. 1859-61) and Auerbach's *Professor's Wife*; and he edited Grotius 'De Jure Belli' (1853) and the mathematical works of Barrow (1860). Isaac Todhunter has written *W. Whewell: an Account of his Writings* (Lond. 1876, 2 vols.), and a formal Life by Stair Douglas and W. Aldis Wright is promised.

Whey is the portion of milk which separates as a thin, greenish, clouded liquid, when by the addition of rennet, as in cheese-making, or other acid substance, the milk curdles and the casein portion takes the form of curd. The W. carries with it the greater part of the milk-sugar and some portion of nitrogenous matter in the form of albumen and lacto-protein. By boiling the W. the greater part of the latter constituents can be separated as a nutritive thick white scum which rises to the top of the fluid, and the remaining liquid is used for feeding pigs, &c., or it may even be drunk with advantage and used in place of water for making Scotch porridge. Alum W. used in diarrhœa is prepared by coagulating milk with alum and separating the W. And the orange and lemon W. used in medicine are made by coagulating with citric acid, and flavouring the resulting W. with orange or lemon peel.

Whid'ah (corruptly 'Widow') **Bird**, the name given to a species of *Insessorial* birds allied to the Weaver (q. v.). It inhabits W. Africa, and is noted for the peculiar development of the tail-feathers. The webs of the two central feathers are very broad, and the shafts protrude without a web. The next two feathers—one on either side—are extremely long, and may measure upwards of 10 inches in length. This disposition of feathers is typical of the broad-shafted W. B. (*Viduia paradisea*), which attains a length of 5 or 6 inches, and is of a brown-black hue above, and pale buff below, with an orange collar. The Shaft-tailed W. B. (*V. regia*) is so named from its four central feathers presenting the bare shafts without any web. The colour is a dark brown, and the length from 9 to 10 inches.

Whig and Tory, the political designations that, superseding the older 'Roundhead' and 'Royalist,' were fastened upon the petitioners and abhorrers of the Exclusion contest (1679), and that after continuing in vogue for 150 years have in turn been almost superseded by 'Liberal' and 'Conservative.' *Whig* had been applied as early as 1648 to the Covenanters, but authorities differ as to its etymology, Defoe maintaining 'the word to be taken from a mixed drink the poor men drank in their wanderings, composed of water and sour milk' (*whey*); Bishop Burnet asserting that western drovers 'were called Whiggamores, and shorter Whiggs, from a word *whiggam*, used in driving their horses;' and a third derivation being from the initial letters of the Puritan motto, 'We Hope In God.' *Tory*, on the other hand, is said to come from the Erse *toir* or *thabhair*, 'to give,' and to have been the 'Stand and deliver' of the Irish Rapparees or Popish outlaws, from whom it was transferred to supporters of the 'Popish Plot.'

Whim'brel (*Numenius phæopus*), a species of *Grallatorial* or wading bird, allied to the Snipe (q. v.). The bill is curved from the base, and the upper mandible projects over the lower. The first quill is the longest, and the tail is short and even. The tarsi have narrow scales in front, and the hinder toe is slender and partially rests on the ground. The W. is known also as the Jack Curlew and Half Curlew. In the Shetland Isles it is named the 'Tang Whaap.' The W. has a brown-tinted plumage. The average length is about 16 inches. In Sussex the bird is called the 'Titterel,' from the cry.

Whin or **Whin'stone**, a name given by miners and others in Scotland to various hard crystalline rocks, of igneous or metamorphic origin, especially greenstone or Diorite, and sometimes, though rarely and locally, applied even to granite.

Whin'chat (*Pratincola rubetra*), an *Insessorial* bird allied to the Stonechat (q. v.), and named from inhabiting furze or 'whin' bushes. The average length is 5 inches. The W. is brown above and buff beneath. The throat is white, and the tail is white at the base, a white stripe extending from the chin to the shoulder. The bird is captured in autumn as a table delicacy, when fat and in good condition. It arrives in Britain in the middle of April, the young being born at the end of May or in the beginning of June. The nest is built on the ground, and contains from four to six eggs of bluish-green hue speckled with brown.

Whipp'ing, a form of corporal punishment once common in this country, but now rarely resorted to, except in the case of boys under sixteen, and in the case of robbery, assaults with intent to rob, &c., according to 26 and 27 Vict., c. 44. This Act does not apply to Scotland, where no crime against person or property is punishable in this manner. The most severe form of W. formerly existed in Russia, where the knout, a whip of plaited thongs interwoven with wires, was greatly used. The pleti, a kind of lash, has been substituted for this instrument of torture. W. is abolished as a criminal punishment in the greater part of the United States. In ancient Rome, scourging was considered the deepest dishonour, and might not be administered to a citizen. The advocates of W. contend that it is more effectual as a restraining influence with a certain class than imprisonment.

Whip-poor-Will, the name—derived from the cry of the bird—of the *Chordeiles vociferus*, a species of *Caprimulgidæ*, or Goatsucker (q. v.), inhabiting the United States. The average length of this bird is about 10 inches, and its plumage is dark, with a white band on the throat. The W.-P.-W. has all the characteristics of Fissirostres (q. v.), and captures insects on the wing. Its flight is near the ground, and takes place in zigzag fashion. The Chuck-Will's-Widow (q. v.), an allied species, occurs in the southern parts of the United States.

Whirl'pool, a vortex or eddy produced by the meeting of two or more different currents of water. Such phenomena are frequent along broken coasts, but then they exist only on a small scale. A large W. would, no doubt, be as dangerous to navigation as whirlwinds are to property on land; but their danger is probably much over-rated. The famous Malström (q. v.) is hardly a W. at all, but simply a strong current; and the same was probably the case with the fabled Charybdis (see SCYLLA). Whirlpools are special instances of vortex motion, and have the essential characteristics of all rotatory motion in fluids. See WINDS.

Whirl'wind, a vortex column of air similar in character but much less extensive than typhoons and storms of all types (see WINDS). The meeting of two or more differently directed currents of air is the cause of all whirlwinds, which invariably have a progressive as well as a whirling motion. The more rapid this whirling motion the more destructive in its effects is the W. It occurs most frequently in tropical countries where the thermal states of the atmosphere are most favourable for their production. In advancing over a desert the W. is accompanied by a column of sand and dust; and somewhat similar in its formation is the liquid column which is the essential character of a Waterspout (q. v.).

Whis'ky (Gael. *uisge*, 'water'), a spirit distilled from grain, 'raw' or malted, and largely used as a beverage and intoxicant in northern climates, particularly in Scotland and Ireland, of which it is the national drink—'the wine of the country.' It is known under various distinctive names, having reference generally to the localities where the manufacture is carried on, such as Islay, Glenlivet, and Campbeltown in Scotland; while in Ireland there are distilleries situated in various parts of the country, but those of Dublin, Banagher, and Cork hold the leading position. W. is made principally from barley, the finest qualities of which are used for that purpose; and the manufacture consists of two distinct processes—that of fermentation, by which a fermented liquor is produced; and distillation, by which the spirit is obtained from the fermented liquor. The process of fermentation is precisely the same as that utilised in the brewing of ale and beer, but the mash may be prepared with unmalted as well as malted grain. The products of the distillation are different according to the class of still in which the operation is conducted. When distilled in the common pot-still the first product is 'low wines,' a weak alcoholic solution which must be submitted to repeated distillation or rectification till it attains sufficient strength and purity. When the 'attenuated worts,' as the fermented liquor is called, is distilled in the coffey-still, the spirit is obtained at one operation in a concentrated condition, and the W. so made is known as 'silent' spirit on account of its freedom from the flavour that characterises 'Pot W.' What is known as 'proof spirit,' the standard by which duty is levied and alcoholic strength gauged, consists of almost equal parts of pure alcohol and water, the proportion of alcohol being 49¼ by weight. The strength at which W. is ordinarily 'bonded' or placed under charge of customs officials is 11 per cent. overproof, so that it can be stored for several years for the purpose of maturing before it falls below proof strength. As usually sold by retail dealers, it is from 10 to 20 per cent. under proof.

The duty on spirits is a large source of revenue to the government of this country, the rate being 10s. per proof gallon. In Ireland W. was first subjected to fiscal regulations in the reign of Charles II., when in 1661 an excise duty of 4d. per gallon was charged, which in 1717 was increased to 8d. That duty in 1719 produced a revenue of £5785. The increase in the consumption is shown by the fact that in 1791, by which time the duty had been increased to 1s. 2d. per gallon, the amount realised from it was £204,648. In 1814 the duty had been raised to 5s. 6d., and shortly afterwards to 6s., but the high rates gave rise to a large amount of smuggling and illicit distillation, and consequently the duty was again reduced to 2s. 4d. per gallon. In Scotland the experience of the high rate of duty previous to that time had been the same,—that it led to an extensive defrauding of the revenue, particularly in the Highlands, where the facilities for illicit distillation were very great, and in 1823

the duty was similarly reduced, with the effect of largely increasing the quantity on which duty was paid. Since then the duty has varied frequently until about 1860, when it was fixed at 10s. per proof gallon, at which it still remains. From the beginning of the present century, the consumption of spirits has increased to a very remarkable extent. In 1800 the quantity of home-made spirits charged with consumption duty in the United Kingdom was—

England	4,352,888	imperial gallons.
Scotland	1,277,596	„
Ireland	1,330 500	„
	6,960,984	„

yielding a total amount of duty of £1,370,054. By 1825 the quantity had increased to 18,928,342 gallons, yielding a duty of £3,884,830, while in 1850 the quantity was 23,862,585 gallons, yielded £5,948,467. In 1875 the quantity consumed was—

England	16,737,366	gallons.
Scotland	6,990,170	„
Ireland	6,094,038	„
	29,821,574	

Later years show rather a decrease in the quantity consumed. In 1878 the quantity of home-made spirits paying duty for consumption was 29,358,715 gallons, being 529,461 gallons less than in the preceding year. The excise duty on spirits for the year ended 31st March 1878 amounted to £15,313,276.

Whist, the most intellectual if not the most popular of all card games. It is of English origin, although within recent times it has become fully naturalised throughout Europe. The number of special W. clubs in existence, and the fact that the members of these clubs belong to all ranks of society, are sufficient proofs of the hold which the game has taken on the country of its birth, and of the intensity of its intellectual attraction. Of Continental countries, France is pre-eminently the land where W. has been adopted with favour. The greatest of all players was Deschapelles, and the most elaborate works on the game have issued from France. There is no spot, however, in the whole earth where W. has not been carried as part of European culture. A collection of *W. Studies* was recently published within the tropics; the game forms one of the common winter resources of the inhabitants of British N. America, while in the Australian wilds the farmers play for sheep points with a bullock on the rubber.

The principal feature of modern W. is the cultivation of the relations between the partners in playing what is called the 'combined game.' A player must consider his own hand not independently but in conjunction with his partner's. Obvious as are the advantages of this plan, it only lately came into practice. Of course, as there are several different modes of trick-making, community of system is essential between partners. Dr. Pole shows clearly that the only system which is favourably adapted to a combination of hands, is that of making tricks by 'establishing' and 'bringing in' a *long suit*. For example, if one holds six spades, after a few leads of the suit, he is likely to be left with full command of it, and every card, however small, will then make a trick unless it be trumped. Out of this theory, indeed, arise all the more important of modern rules. Take, for instance, the *management of trumps*, which is so great a difficulty to unsystematic players. The chief obstacle in making long suits is the risk of their being ruffed, and the advantage will be with the party who, having a greater number of trumps, can succeed in drawing those of his adversaries. Five trumps are generally sufficient for this purpose, and hence the rule that, when holding this number or more, one should lead them. Three or four leads will generally disarm both your opponents, and you will still have one or more left to bring in your own or your partner's long suit. Thus, so important becomes the trump lead, that in the modern game a conventional signal or *call for trumps* has been introduced, by which, if the holder of a strong trump-hand cannot get the lead early, he may intimate his strength to his partner and request him to lead in trumps. With three trumps or less a trump lead at the beginning of the game is seldom justifiable; with four much discretion is required in leading. The greatest mischief one can do to a partner's strong trump-hand is by forcing it to ruff, to deprive it of its preponderating strength. On the same principle it is the game to force a strong adverse trump-hand, or, when without any of the required suit, as second player to a trick which it is impossible for your partner to take, to ruff fearlessly if weak in trumps, but to pass the trick if strong. In the former case one's trumps are useless; in the latter, they are more valuable in reserve. The theory gives sure guidance in the *management of plain suits*. The most important *lead* is the first, and in consonance with the theory, it should be calculated as closely as ignorance of the partner's cards will allow, to favour the combined hands, and at the same time to convey to the partner some idea of one's own cards. The lead from the long suit fulfils these conditions, and if the player do not succeed in bringing in the suit, the lead is at all events his safest, for it does not deprive his remaining cards of any advantage resulting from collective strength. Wide experience and close reasoning have determined that of one's long suit it is most generally expedient to begin with the lowest; this gives the partner a chance of making the first trick, and reserves for the player the complete command of the suit subsequently. When one holds several high cards, however, this rule is modified in consideration of the chance of the suit being trumped, and of other contingencies. Certain definite leads have therefore been determined upon for particular combinations. Of these the most useful are the following (all the important cards held being stated in the order of play): king and ace; king and queen; ace, queen, and knave; queen, knave, and ten; ten, king, and knave. The lead of king from king and ace is one of the signals or conventional refinements of modern play. The modern theory further defines the duty of a partner in regard to one's long suit; after showing you his own he should return yours, and in doing this he must *get rid of the command* by playing out his master cards if he holds them. Then, secondly, he must adopt *strengthening* play; for instance, suppose he had originally ace, knave, and four, and has won your first lead with the ace, he must return the knave and not the four. The effect is to raise the rank of your lower cards and to aid in getting lighter ones out of the way. By the new system the second player is bound to play his lowest card, except in certain recognised and well-defined cases. Even the fourth player, easy as his part is, may do great mischief by irregular treatment of small cards or sequences. Convention prescribes that, in playing worthless cards, the lowest shall fall first; from this a partner's inference is that you have nothing smaller. In returning your partner's suit, when you only hold useless cards, you must return the highest if you have only two left; the lowest, if more. The *call for trumps* is given by throwing away unnecessarily a higher before a lower card, *i.e.*, by a recognised departure from the ordinary rule. The legitimacy of this signal has been questioned, but it has already found its way into extensive use, and it is difficult to see any sound objection to a convention which has not been privately arranged, and which is therefore as significant to an adversary as to a partner. In addition to the rules referred to, a few may be given here; rules and descriptions of the game abound in W. books. An important rule is to lead your own suit before returning your partner's, *unless he leads trumps*, which return immediately. Again, in returning your partner's suit, if you have only two left, play the highest; if more, the lowest. In any position, if you hold the best card, play it in the second round. *Holding five trumps, lead them* or call for them. Watch for your partner's call for trumps, especially if you are weak in them. Do not trump a doubtful trick second in hand if you hold more than three trumps; with three or less trump fearlessly.

The early history of W. is involved in obscurity, but as early as the 16th c. a card game was commonly played which was not only called by a name still used in W., but which had one element in common with the modern game. *Triumph* (corrupted into *trump*) took its peculiar character from the predominance of one particular suit over all others, and this suit was called the triumph or trump suit. Triumph was of Continental origin, a work published in Italy in 1526 speaking of it as *Trionfi*, and Rabelais including *la Triumphe* among the games played by Gargantua. That the game early became popular in good English society is evident from its being used as a similitude by Latimer in a sermon preached at Cambridge in 1529. The divine uses both the original and corrupt appellation of the game. At a later period references to it are more frequent; worthy of note are those in *Gammer Gurton's Needle*, and in Shakespeare's *Antony and Cleopatra*, act iv., sc. 12. Triumph appears to have been played in several ways; in some forms it resembled the present Écarté. To W., except in the predominance of the trump suit, it bore little

resemblance. About the beginning of the 17th c. the game had taken another name, which is also preserved in W., namely, *Ruffe.* Cotgrave, in his *French and English Dictionary*, 1611, defines the French word *triomphe* as 'the card-game called ruffe or trump;' and Nares in his *Glossary* says 'ruff meant a trump card, *charta dominatrix.*' The game itself had by this time departed considerably from the foreign type, certain advantages or 'honours' having been added to the four highest trump cards. To distinguish between the old and new forms of the game, the one was called 'French ruff,' and the other 'Ruff-with-honours.' The latter was played with 52 cards, the highest being the ace. There were four players, or two sets of partners. Each got 12 cards; the remaining four were left on the table as a stock, and the top one was turned up to determine the trump suit. The player who held the ace of trumps could take the stock in exchange for four cards of his own, an operation called *ruffing.* Three honours in the joint hands were reckoned as equivalent to two tricks, and four honours to four. This was a near approach to the modern game, to which it was still more closely approximated by further changes, as well as by the radical alteration in the name, effected early in the 17th c. The first form of the new designation was *Whisk*, a word which occurs in Taylor the Water Poet's *Motto*, published in 1621. The derivation of the word is very doubtful, but it has been suggested that it was originally used by the common people as a synonym for *ruff*, in ridicule of the article of dress then so fashionable. Some thirty years later the name had assumed its present form, of which the earliest known literary use is quoted by Johnson from the second and spurious part of *Hudibras*, published in 1663. A curious book, *The Compleat Gamester, &c.*, bearing date 1674 and ascribed to Charles Cotton the poet, contains a description of 'Ruff-with-honours (*alias* slamm) and W.,' which are stated to be 'games so commonly known in England, in all parts thereof, that every child almost of eight years old hath a competent knowledge in that recreation.' After describing Ruff-with-honours, the author says, 'W. is a game not much differing from this.' The ruffing privilege was then abolished; each player still had 12 cards, but instead of leaving an unknown stock on the table, the four deuces were discarded before dealing. Cotton, who never alludes to the earlier name Whisk, says 'the game is called W. from the silence that is to be observed in the play.' This derivation has passed into common acceptance, but the older word, 'whisk,' remained in use for a century after Cotton wrote. Johnson says W. is 'vulgarly pronounced whisk;' but the Hon. Daines Barrington, writing (1786) on card games, adopts without qualification the latter orthography. During the 18th c. the game was chiefly played in low society, and great part of Cotton's chapter is devoted to an exposure of the tricks and frauds with which it had become associated. It was rescued from obscurity by a party of gentlemen, including the first Lord Folkestone, who began about 1730 to play regularly at the Crown coffee-house in Bedford Row. Edward Hoyle, probably one of the party, appeared about this time, and gave to W. its permanent, logical, scientific shape. Little is known of Hoyle, except that he was born in 1672, described himself as 'a gentleman,' moved in good society, and, with the object of exciting a legitimate interest in W., took to teaching it professionally. His written instructions to his pupils were sold in MS. at a guinea a copy, and these having been pirated, the author, to secure his copyright, published them under the title of *A Short Treatise on the Game of W., &c.* (Lond. 1743). Sixteen editions of his work had appeared before the author's death, which took place on 29th August 1769. From this time W. advanced rapidly in public favour, finding its way to Court (about 1754) and to the Universities, as appears from No. 33 of the *Idler* (1758). At Bath, then, one of the chief seats of W., and the scene of the exploits of Nash and such celebrities, there issued about 1800 a sound, practical work entitled *Advice to the Young W. Player*, by Thos. Matthews. It contained many improvements, resulting from the experience of half a century. About the same date an important change took place, namely, the introduction of 'Short W.' by reducing the winning score from ten to five, and abolishing the 'call' for honours when wanting two of game. The new form came quickly into favour, and has for many years entirely superseded Long W. in the best circles. Translations of Hoyle early carried W. into France, where it was played by Louis XIV., and, under the Empire, was a favourite game of Josephine and Marie Louise. After the Restoration a French writer remarked that 'the nobles had gone to England to learn to think and had brought back the thinking game.' The great player of the day was Talleyrand, and a commonplace in W. books is his *mot*—'You do not know whist, young man? What a sad old age you are preparing for yourself!' In 1839 M. Deschapelles published his *Traité du Whiste*, the fragment of a larger work which never appeared. The next important step in the development of the game was taken during the decade 1850–60, when a youthful coterie at Cambridge set themselves to a rigorous examination of its scientific scope. Since the general adoption of Short W. the widespread practice in playing had led to many minor improvements, but still players were guided by the precepts of Hoyle and Matthews. The little W. school formed at Cambridge held together in London, and in 1862 one of its members, 'Cavendish,' issued his celebrated work, *Laws and Principles of W.* (12th ed. 1879), which illustrates the modern play by a set of model games, giving detailed rules for practice. Two years later appeared *A Treatise on Short W.*, by the late Mr. James Clay, M.P., forming an able commentary on refined points of the best modern play. Dr. Pole, in *The Modern Scientific Game of W.* (Lond. 1865; 8th ed. 1877), expounds the fundamental W. theory, and in an article in the *Fortnightly Review* for April 1879, entitled *Conventions at W.*, discusses the legality of signals. Hayward, *Biographical and Critical Essays* (new series, Lond. 1873); Ebersberg, *Das edle W.* (7th ed. Vien. 1877); and Colonel Drayson, *The Art of Practical W.* (Lond. 1879).

Whis'ton, William, an English theological writer, born 9th December 1667, at Norton in Leicestershire, was the son of the rector of the parish. He studied at Cambridge, where he took his degree in 1690 and obtained a fellowship in 1693, distinguishing himself particularly in mathematics. In 1696 Bishop Moore of Norwich appointed him his chaplain, in 1698 he became vicar of Lowestoft, and in 1703 Sir Isaac Newton helped to procure him the Lucasian professorship of mathematics which he had himself resigned. The zealous profession which W. soon afterwards made of Arianism caused his expulsion from the university in 1710; and soon after being practically, though not formally, cut off from the Church of England, he first formed a society for the study of primitive Christianity, and afterwards joined the General Baptists. Till his death, 22d August 1752, he continued to advocate his peculiar doctrines by tongue and pen. W.'s chief works are *New Theory of the Earth, from its Original to the Consummation of All Things* (Lond. 1696), written in opposition to Burnet's theory; *The Accomplishment of Scripture Prophecies, being the Boyle Lectures for* 1707 (Lond. 1708), in which he maintains that all prophecies have but one meaning; *Prælectiones Physico-Mathematicæ* (Camb. 1710), being a popular explanation of the Newtonian philosophy; *Historical Preface to Primitive Christianity Revived* (Lond. 1710), the work which caused his condemnation by convocation; *Primitive Christianity Revived* (Lond. 5 vols. 1711–12), in which he maintains the authenticity of the *Apostolic Constitutions*, *Vindication of the Sibylline Oracles* (1715); *Hist. Memoirs of Dr. Samuel Clarke* (1730); and *The Genuine Works of Flavius Josephus, translated from the Original Greek* (1737). This last work has been remarkably popular, but is the only one of W.'s fifty productions of which popularity can be predicated. See *Memoirs of Mr. William W., written by Himself* (Lond. 1749–53); Farrar's *Critical Hist. of Free Thought* (Lond. 1863); Hunt, *Religious Thought in England* (Lond. 1873).

Whit'by, a seaport in the N. Riding of Yorkshire, 54½ miles E.N.E. of York by rail, stands looking northward over the German Ocean, just where the Esk, leaving its wooded dells, forms a broad tidal pool walled in by jet-veined cliffs of alum shale. Under and creeping up these cliffs lies the old fishing-town, with quaint wooden-gallleried houses; above to the W. are the fashionable terraces of Hudson, the Railway King (1845); and the loftier E. cliff is crowned by the ruins of the matchless Abbey, the gables namely of its Early English choir, with row upon row of exquisite lancet windows, the northern transept, and part of the pure Decorated nave—all until 1830 surmounted by a great central tower. A cruciform Norman church, gained from the town by a flight of 190 steps, crouches in picturesque unloveliness beside the Abbey, to whose S. is the 16th c. W. Hall. None of four modern churches has any beauty, but the Catholic chapel is a good Early English structure, harmonising better with

its surroundings than does a red brick Concert Hall (1878) in 'Queen Anne' style. The outer harbour is sheltered by two stone piers, 215 and 520 yards in length, on the western and longer of which a lighthouse stands, and a museum with a splendid collection of native fossils. The whale-fishery (1733–1837) has quite died out, but coal-shipping and the herring fishery employ (1879) 206 coasters and 268 fishing-boats, while in 1878 there entered 797 vessels of 103,790 tons, and cleared 749 of 92,982 tons, the imports of foreign and colonial produce amounting (1877) to £4872. A W. 'prentice, Captain Cook, chose W.-built vessels as 'the best and stoutest bottoms in England' for his great circumnavigation of the globe, and W. shipyards keep up their ancient fame, turning out (1874–78) 26 iron steamships of 21,839 tons. But the jet manufacture, employing some 1500 persons, and with an annual value (1876) of nearly £100,000, is Whitby's specialty, and the alum manufacture, sailmaking, and rope-spinning are largely carried on. W. returns one member to Parliament, and publishes two weekly newspapers. Pop. (1871) 13,094, a number likely to be much increased by the opening of the railways to Scarborough and Saltburn. In 657 St. Hilda founded her double house for nuns and monks at Streoneshalk (the 'Lighthouse Bay'), and hither in 664 King Oswi summoned the champions of Roman and Celtic rites to the famous Synod in which Rome's victory, won by St. Wilfrid over Colman, rescued the English Church from her Irish sister's chaos. Here Cædmon lived and died, and here St. John of Beverley was bred. The ammonites of the Scar, those headless snakes changed by her prayers into a coat of stone, preserve St. Hilda's fame; but in 867 the Danish Vikings not only burnt her Abbey, but altered the very name *Streoneshalh* to *Whit-* or *Priest-by* ('white' or 'priest's house'). William de Percy in 1073 refounded the Abbey under the Benedictine rule, not for the mythical nuns of *Marmion*, but monks alone. With Scott's great poem and Mrs. Gaskell's *Sylvia's Lovers* (1863) most readers are familiar, and further reference may be made to the works cited in F. K. Robinson's *W. Glossary* (English Dialect Society 1876), itself containing much curious local information.

Whit'church, a town of Shropshire, England, 20 miles N.E. of Shrewsbury by rail. It has a handsome parish church, built in 1772, several dissenting chapels, and trade in hops. Pop. (1871) 3696.

White, Gilbert, a celebrated English naturalist, belonged to a family which as far back as 'the reign of Elizabeth possessed the estate of Swan Hall in Oxfordshire,' and was born 18th July 1720, at the village of Selborne in Hants, which he was destined to render as famous as himself. The young man, who had been under the tuition of Dr. Thomas Warton, father of the better-known Thomas and Joseph Warton, entered Oriel College, Oxford, in 1739, and having become bachelor of arts in 1743, he obtained in the following year a fellowship in his college, which he kept all his life. Receiving deacon's orders in April 1747, he shortly afterwards became curate to an uncle at Swarraton, and in 1751 he removed to the curacy of Selborne. Though in 1758 he accepted from his college the living of Moreton Pinkney in Northamptonshire, he never entered upon residence there, but steadily refusing all further preferment, continued to live a peaceful and uneventful life in the village of his choice, relieving its monotony by not unfrequent visits to London, and finding work enough for even its slowest hours in studying the habits of the animals around him. He died June 26, 1793. His great work, *The Natural History and Antiquities of Selborne*, first published in 1789, is unique in its kind. With all the moral and literary charm of Walton's *Complete Angler*, it unites a scientific accuracy of observation to which Walton can lay no claim, and it consequently continues to be equally in favour with the professional naturalist and the ordinary reader. In the present century it has run through upwards of *thirty* distinct editions, the most recent of which are Bennett's (1874), Buckland's (1875), Harding's (1876), and Bell's (2 vols. Lond. 1877). Mr. Bell, who himself has lived in Selborne for thirty years, has collected all recoverable particulars about the author, and printed for the first time a number of his letters, memoranda, and poems. Of special interest are the letters to his brother, John W., who was chaplain at Gibraltar, and corresponded with Linnæus.

White, Henry Kirke, a butcher's son, was born at Nottingham, August 21, 1785. Precocious talents did not promise to raise him from the rank in which he was born, for he was destined for his father's business, and after school hours delivered meat to customers. His gorge rising at the butchering, he was engaged to a hosier, but, sick of folding stockings, he was apprenticed at last to a solicitor. During leisure hours he mastered half-a-dozen languages. After a few trials in magazines, W. in 1803 published a volume of poems, which remained unnoticed save by a few. Southey and Simeon got him sent to St. John's College, Cambridge, where his brilliant but brief career was ended by consumption, October 19, 1806. Southey published his *Remains*, with a Memoir (3 vols. 1807–22). W.'s verses exhibit a pure, sensitive soul expressing itself in delicate language, but it was in his sad story that the real poetry lay.

White, Joseph Blanco, was born of Irish extraction at Seville, July 11, 1775, and entered at eight his father's counting-house. Hatred of business caused his removal to the Dominican College (1789), whose odious system of scholastic philosophy he presently exchanged for the more congenial Jesuit teachings of the University; and finally, 'with the priesthood forced on him as the indispensable condition of an intellectual life,' he became a sub-deacon (1796). By 1802 he had lapsed from a strong devotion to total unbelief; but in England, his refuge from the French invasion (1810), a perusal of Paley's *Natural Theology* left him convinced of the truth of Christianity; and in 1814, subscribing the Articles, he became a clergyman of the English church. To instance a few more phases of this shifting soul, in 1818 he distinctly abandoned, in 1825 resumed belief in, our Lord's divinity, in May 1834 disapproved denials of the Trinitarian doctrine, and within eight months turned Unitarian. Quitting the palace of Archbishop Whately, where he had lived for some time past, he removed to Liverpool, and there died, May 20, 1841. *A Sonnet to Night* by him lives, while his *Letters from Spain, by Don Leucadio Doblado* (1821) and *Practical and Internal Evidence against Catholicism* (1825) are long forgotten; his posthumous *Autobiography* (3 vols. Lond. 1845) presents a singular picture of an honest and rarely-gifted, but morbid and vacillating, character. See vol. ii. of Gladstone's *Gleanings from Past Years* (Lond. 1879).

White'bait (*Rogenia alba*), a famous species of Teleostean fishes allied to the Herring (q. v.), and distinguished by the presence of teeth on the palatine bones and pterygoids, while the vomer and tongue are also provided with teeth. The W. is usually associated with the ministerial fish-dinner at Greenwich, and is accounted a great delicacy, its flesh being tender and palatable. In spring and summer it occurs at the estuary of the Thames, but is also caught on the S.E. coasts of England in winter. The average length is 5 inches. The W. is eaten fried with bread crumbs. Young herrings and pilchards are often cooked as W. The body resembles that of the herring, but is more compressed.

White'boys, a secret association formed among the Irish peasantry in the beginning of the reign of George III. to resist the enclosure of common land, received its name from its members wearing white smocks during their nightly raids. From demolishing fences the W. proceeded to demand the abolition of tithes and similar grievances, and to the perpetration of agrarian outrages, which led to the appointment of a special commission and the execution of the ringleaders (1762).

White Colours. The principal white pigment, and the most important of all painters' colours, is white-lead (see **Lead**). Baryta yields several commercial varieties of W. C., largely used for adulterating white-lead. The substances used are heavy spar, the native sulphate, and witherite, the native carbonate of baryta. An artificial sulphate of baryta is also used in permanent white. Zinc white or Chinese white is a hydrated oxide of zinc, and pearl white is yielded by the nitrate of bismuth. A fine chalk yields Spanish white, and whiting is ordinary ground chalk. Quicklime is a sanitary white for external walls, &c.

White'field, George, the founder of one of the two great divisions of Methodism, was born at Gloucester, where his father was an innkeeper, March 16, 1714. He was educated at the

grammar-school of St. Mary de Crypt in his native town, and was admitted a servitor of Pembroke College, Oxford, in 1733. Here he became acquainted with John and Charles Wesley and their associates, who had been for some years known in the University by the name of 'Methodists.' W.'s enthusiastic temperament soon carried him beyond all his companions in the austerity of his asceticism and in devotion to works of charity. Failing health obliged him to return to Gloucester, where he was ordained a deacon by Bishop Benson (June 1736). He preached his first sermon with striking effect in Gloucester Cathedral, and in the same year took his degree of B.A. In 1737 he visited London, where his preaching attracted immense crowds and produced the most extravagant physical effects on many of the hearers. In December of the same year, on the urgent invitation of the Wesleys, he left England for Georgia, where he remained for nearly a year. He now returned to England in order to raise subscriptions for an orphan-house which he had established in Georgia, and commenced a series of preaching-tours in conjunction with Wesley, the result of which was the formation of the Methodists into a separate and powerful sect. In 1739 he again visited America, remaining for nearly two years. In 1741 the two leaders quarrelled on the question of predestination, Wesley declaring for Arminianism and W. for the Calvinistic dogma of irresistible fate and eternal election and reprobation. In the same year W. visited Scotland on the invitation of the Secession leaders Ralph and Ebenezer Erskine, whom, however, he soon offended by his blindness to petty differences and his readiness to preach in parish churches as well as in secession pulpits. In the October of 1741 he visited Wales, where he married a widow, with whom, however, he did not live happily, and whose death in 1768 'set his mind much at rest.' His supporters now built him a large 'Tabernacle' at Moorfields, where he attracted, as before, immense audiences. In 1744 he went again to America, and continued his preaching-tours, everywhere with the same effect. In 1758 he returned to London, and soon afterwards made a convert of Selina, Countess of Huntingdon, who made him her chaplain and extended his fame to the highest circles of rank and literature in London. Among his hearers were to be found Chesterfield, Bolingbroke, and Hume, and in America he was listened to with pleasure by Benjamin Franklin. W. was now at the height of his fame. His audiences were numbered by tens of thousands, and his preaching was marked to a large extent by more than momentary effects. Though much of his labour was wasted in awakening the multitude to a sense of the wickedness of fictitious crimes, yet valuable ethical results followed also. Franklin bears witness to 'the change made in the manners of our inhabitants.' W. set out on his seventh visit to America in 1769, and died suddenly, soon after his arrival, at Newberry, near Boston, September 30, 1770. From an account-book in which he entered his 'collections,' it appears that he preached upwards of 18,000 sermons to 10,000,000 of people. From the writings he has left behind him it is impossible to understand the marvellous effect of his preaching. With no ideas whatever, and with but a limited stock of Biblical phrases, his sermons told upon his audiences like a succession of electrical shocks. In the words of his latest biographer, 'his theological learning was comparatively small; he had no genius, no poetry, no profundity of thought, no embellishment of language, no dramatic illustration, and it may fairly be doubted if he ever understood the Calvinism which he preached,' and yet he has been perhaps the most powerful of English preachers. The intense energy of his convictions and the vehemence of his manner appear to have been the spell which overawed his auditors. 'What he says and does,' says Doddridge, 'comes but little short of an assumption of inspiration or infallibility.' He owed everything to the peculiarity and novelty of his manner, and the dictum of Dr. Johnson must be allowed to stand, that here 'familiarity and noise claimed the praise due to knowledge, art, and elegance.' A collection of his sermons and letters was published the year after his death, *The Works of Rev. G. W.* (6 vols. Lond. 1771), and his *Memoirs* by Dr. Gillies (1772). See *The Life of the Rev. G. W., B.A., of Pembroke College, Oxford*, by the Rev. L. Tyerman (2 vols. Lond. 1876).

White'fish (*Coregonus albus*), a species of Teleostean fishes, belonging to the family *Salmonidæ*, and occurring in the rivers and lakes of N. America. The W. belongs to the same genus as the Vendace (q. v.), pollan, &c. The average length is 2 feet, and the colour a bluish grey above and white beneath. It may attain a weight of 10 lbs., and has a long body and a pointed muzzle. The mouth is toothless. It is caught in winter by means of nets and also by spearing. The W. is largely eaten by the Indians, both in a fresh and salted state. After boiling, the flesh is white and pale. Lake Champlain appears to be the most southern limit of distribution of this fish: an allied species (*C. Otsego*) inhabits the lake of that name.

White Gun'powder, a white explosive mixture, invented by Augendre and composed of chlorate of potash (2 parts), loaf-sugar and ferrocyanide of potassium (each 1 part), separately pulverised and mixed dry. W. G. has very great explosive power and is readily inflamed, but a liability to explode from a shock or friction and other disadvantages unfit it for practical use.

Whitehall, a village of New York, U. S., at the S. end of Lake Champlain, 70 miles N. of Troy by rail. It has 5 churches, 4 banks, 2 newspapers, and an opera-house. There are 9 timber yards, 8 ship-yards, saw and flour mills, machine and carpet factories. Pop. (1870) 4322. Settled by Major Philip Skene in 1761, it became a military depot in 1812, and has since been important for transport trade.

Whiteha'ven, an important mining centre and seaport of Cumberland, England, is situated on a level inlet between precipitous cliffs, 38 miles S.W. of Carlisle, and 10 miles from Workington by the W. and Workington Railway, through which it is brought into direct communication with London and other parts of England. The town contains numerous churches belonging to the various Protestant denominations, of which the latest (built by the Congregationalists, 1875) has a fine Gothic spire 110 feet high, several schools, a mechanics institute, a library, public baths, &c. There are manufactures of coarse cloth, earthenware, soap, &c., but the prosperity of the town is chiefly due to the immense seams of coal and of hæmatite iron ore in its vicinity, some of which are wrought a distance of two miles under the sea. There are also large rope-works and shipbuilding yards (32 British vessels of 26,652 tons during 1874–78), and regular steamboat communication with Liverpool, Belfast, Dublin, and the Isle of Man. The port (improved by the opening of a new wet dock in 1876) was entered in 1878 by 1632 vessels of 200,679 tons, and cleared by 1646 of 205,723 tons; and on December 31st of same year had 134 ships on its register, besides 59 fishing-boats. In 1877 the imports amounted to £80,545, and the exports to £72,622. W. publishes five weekly newspapers, and returns one member to Parliament. Pop. (1871) 18,451.

White'locke, Bul'strode, born in London, 2d August 1605, from Merchant Taylors' passed to St. John's College, Oxford, and thence degreeless to the Middle Temple. Returned to the Long Parliament of 1640, he acted as chairman of the committee for drawing up Strafford's charges of impeachment, and was one of the commissioners appointed to treat with the king at Oxford; but during the Troubles he steered a uniformly middle course, as member of the Westminster Assembly (1643) opposing the adoption of Presbyterianism, as governor of Windsor (1644) saving the royal library and cabinet of medals from dispersion, and as a commissioner of the Great Seal (1649) withholding his consent to Charles's death. Ambassador to Sweden (1653), he concluded a treaty with Queen Christina, and by her was made knight of the order of Amartha, on his return becoming a commissioner of the Treasury (1655), Speaker of the House of Commons (1656), and one of Cromwell's lords (1657). He helped, however, to dethrone the Protector's son, and after the Restoration lived unmolested at Chilton Park, his Wiltshire seat, where he died, 28th January 1676. From his MSS. have been published *Memorials of English Affairs from the beginning of the Reign of Charles I. to the Restoration* (1682, new ed. 4 vols. Oxf. 1852); *Memorials of English Affairs from Brute to the end of the Reign of James I.* (1709), *Journal of the Swedish Embassy* (1772, new ed. 2 vols. 1845), and other works.

White Mountains, a mountain-range of Maine and New Hampshire, U.S., belonging to the Appalachian system, and covering a total area of 800 sq. miles. The chief summits are Mount Washington (6288 feet), Mount Jefferson (5794 feet), Mount Adams (5714 feet), Mount Madison (5363 feet), Mount Pleasant (4712 feet), &c. The W. M. are much frequented by

tourists on account of their wild and beautiful scenery, which has won for the region the name of the 'Switzerland of America.' Here rise the head-waters of the Connecticut and Merrimack rivers. The engineering marvels are numerous, the chief being the railway which climbs up Mount Washington to the hotel on its summit.

White River rises in the Ozark Mountains on the borders of Arkansas and the Cherokee Territory, flows N.E. into Missouri to Forsyth, then S.E. through Arkansas, and having been joined by the Big Black River at Elizabeth, falls into the Mississippi 15 miles above the mouth of the Arkansas River. It is navigable to Batesville, 380 miles from its mouth, and is in all 900 miles long.

White Sea (Russ. *Byeloye More*), a branch of the Arctic Ocean which extends S.W. into the government of Archangel as far as the 64th parallel. It is separated from the open sea by the peninsula of Kola and a strait 246 miles long, and from 106 miles (between Capes Sviatoi and Kanin) to 28 wide, and divides itself for the most part into three bays, of which the broadest is the Dwina Bay to the S.E., the southmost the Onega Bay, and the longest the Kandalak Bay in the W. Its area, including the N.E. bay, into which the Mezen falls, is 47,346 sq. miles. The coasts are flat, with numerous lakes, small rivers, and mountains in the N. and E. The W. S. is blocked with ice except during the months of June, July, and August. Canals connect it with the Volga and the Dnieper. The dwellers on its shores are Lapps, Finns, and Samoyedes, who live by fishing, seal-hunting, and the chase. The chief port is Archangel (q. v.). The passage to the W. S. was discovered in 1553 by Richard Chancellor, an officer under Sir Hugh Willoughby. The English in 1584 established the little fort of Archangel as the centre of the W. S. trade, in which they enjoyed great privileges till the founding of St. Petersburg.

White Sul'phur Springs, a favourite summer resort for the inhabitants of the United States, America, on the Chesapeake and Ohio Railway, 227 miles W. of Richmond, in Greenbrier county, W. Virginia. Its medicinal spring, known since 1778, attracts annually great numbers of visitors. In the vicinity are the Red, Salt, and Blue Sulphur Springs, all containing sulphates of lime, soda, magnesia, &c.

White'throat, the name given to various species of Warblers. The Common W. (*Sylvia undata*) and the Garden W. (*S. hortensis*) are familiar examples. The former attains a length of 5 inches, and is of a reddish-brown colour above and brownish white below, the throat being pure white. The Garden W. has the abdomen pure white. The average length is 6 inches. The Lesser W. (*Sylvia curruca*) is dark grey above, and white below. Its length is 5 inches. The food of the W. consists of berries and seeds, and the song is sweet and clear.

White'wash consists of common lime or *whiting* mixed with water to a milky consistency, size being sometimes added. It is used for coating walls and ceilings of stone, brick, or woodwork, and is a valuable sanitary agent.

Whitgift, John, a merchant's son, was born at Great Grimsby, Lincolnshire, in 1530, and educated in London at St. Anthony's school. Trained as a child in Reformation principles by his father's brother, Abbot Robert of Wellow, he matriculated at Queen's College, Cambridge (1549), but speedily migrated to Pembroke Hall, then governed and taught by three famous Protestants—Ridley, John Bradford, and Edmund Grindal. Their patronage brought him a scholarship and Bible-clerkship, and in 1555 he was chosen a fellow of Peter House, whose master sheltered him through Mary's reign. At length Elizabeth's accession permitted his ordination to the Cambridgeshire rectory of Teversham (1560), and under the new *régime* his rise was rapid. As Lady Margaret's professor of divinity (1563), he took for his first text, 'The Pope is Antichrist;' in 1567 he was elected master of Pembroke, in 1570 of Trinity College. Elizabeth herself commended a sermon by styling him her 'white-gift' and by a royal chaplaincy; thanks to her favour, he rose to be prolocutor of Convocation (1572), Dean of Lincoln (1573), Bishop of Worcester and Vice-president of Wales (1576), and Grindal's successor in the archbishopric of Canterbury (1583). Though leaning himself to moderate Calvinism, he zealously upheld the spiritual despotism of the Crown, wielding impartially the terrors of the Ecclesiastical Commission against both Puritans and Catholics. He, the assailant of Cartwright (q.v.) and the assailed in the great 'Mar-prelate' controversy, strove to force Calvinistic supralapsarianism on the Church by his Lambeth Articles (1595), but weakly withdrew them so soon as their tenets appeared obnoxious to Burleigh and the Queen. To the same weakness his rigour may be justly imputed, for personally W. was the reverse of cruel, being a generous patron of learning, and as munificent in his charities as he was princely in his hospitality. The death of Elizabeth was a grievous shock to the archbishop, but alarm concerning her successor's orthodoxy did not prevent his receiving James with fulsome flattery, and his fears were soon calmed by the Hampton Court Conference (q. v.), at which he was present but took no prominent part. Next month he died at Lambeth, 29th February 1604. From his ninety-one MS. and printed productions the Parker Society has issued a selection, edited by the Rev. John Ayre, and including the *Answer to a certain Libel, entituled an Admonition to Parliament* (1572) and the *Defense of the Answere to the Admonition against the Reply of Thomas Cartwight* (1574), two vigorous polemics, where personal ridicule seasons blunt accuracy of style. See Sir George Paule's *Life of W.*, reprinted in Wordsworth's *Ecclesiastical Biography* (vol. iii. 1809), and Dean Hook's *Lives of the Archbishops of Canterbury* (vol. v. new series, Lond. 1875).

Whi'ting is a term applied to ground and elutriated chalk, which is employed as a pigment in size-painting, for cleaning plate, and for other purposes.

Whi'ting (*Merlangus vulgaris*), a species of Teleostean fish belonging to the *Gadidæ* or Cod family. It is destitute of a barbule or tentacle borne on the lower jaw, seen in the cod and haddock, is smaller than the haddock, and of a more elegant shape. The W. is fished on British coasts, the average weight being from 1 to 2 lbs. The body is compressed, and the upper jaw projects beyond the lower. The scales are small, and the dorsal fins number three. There are two anal fins. The colour is a greenish yellow above and silvery white beneath. A black patch occurs at the base of the pectoral fin. The fish is delicate and palatable. An allied species, Couch's W. (*M. albus*), is captured on the British coasts, but seems to be a native of the Mediterranean Sea.

Whit'low, or **Parony'chia**, is inflammation in, or in the neighbourhood of, the sheath of one of the flexor tendons of the fingers. There are various forms of this disease, the common W. consisting usually of a collection of a purulent fluid between the skin and epidermis, and requiring nothing more than the division of the epidermis, followed by plain water-dressing. In other and more severe cases the abscess forms beneath the skin, and should be opened early. When there is acute inflammation inside the sheath of the tendon, the disease is called *periosteal* W., and the disease being a very serious one, prompt and skilful treatment is necessary, otherwise a finger or the hand may be lost. The first symptoms are intense pain generally in the middle phalanx of the finger, with slight swelling and redness. The part is exquisitely tender, and fluctuation can seldom be felt at the early stage of the formation of matter, owing to the tenseness of the part. A free and deep incision in the middle line of the finger is urgently needed whether suppuration has or has not taken place, and this will afford immediate relief to the pain and tension. The incision is very painful, though momentary. The bleeding should be encouraged by putting the hand in warm water. A large poultice should afterwards be applied, and the hand should be elevated on to the opposite shoulder.

Whit'man, Walt, the 'Poet of Democracy,' born at West Hills, Long Island, May 31, 1819, was educated at Brooklyn and New York, and having from printer turned carpenter, from carpenter schoolmaster, made long journeys afoot through Canada and the States (1847-48). Editor for short periods of New Orleans and Huntingdon newspapers, he served as a volunteer nurse in the Washington and Virginian hospitals (1862-65), and held various Government clerkships at Washington till 1874, when, enfeebled by paralysis, he withdrew to Camden in New Jersey. On April 14, 1879, he made his début as a lecturer at New York, his subject being the 'Death of Lincoln.' 'Disorderly, fleshly, sensual' (to quote himself), he has achieved 'a literary

immortality' (to quote Mr. Robert Buchanan) by his *Leaves of Grass* (1855), *Drum-Taps* (1865), and *Two Rivulets* (1873). These 'poems,' devoted to the 'illumination of the Execrable,' resemble if aught a chaotic dictionary—no rhyming one, be it observed—with a few chance beautiful, more nasty terms, while 'as to their meaning it's what you please'—nonsense and filth to the ignorant vulgar, 'ineffable goodness and beneficence' to a few such 'golden eagles' as W. W. W. M. Rossetti has published an English edition of his *Poems* (Lond. 1868). See Bayne in the *Contemporary* (December 1875).—Wholly unconnected with the preceding save by identity of name, **Mrs. Sarah Helen W.** (*neé* Power) was born at Providence, Rhode Island, 19th January 1803, married at twenty-five a Boston lawyer, and left a widow (1833), died at her birthplace 27th June 1878. Her *Hours of Life and Other Poems* (1853), the *Fairy Ballads* (new ed. 1868), written conjointly with a sister, and *In Memoriam* (1878), commemorating that sister's loss, are full of melody and love of nature. The last-named work contains fifteen pieces addressed to Poe, her brief engagement to whom (1848) formed her one romance, and gave birth to her *Poe and his Critics* (1860), a little volume of passionate, lofty prose.

Whit'ney, Eli, an American inventor, was born at Westborough, Massachusetts, December 8, 1765, and graduated at Yale College in 1792. In Georgia, whither he went as a teacher, he devised a machine for cleaning seed-cotton. His invention, however, was stolen by others before he took out a patent. In 1795 he started a machine manufactory with a Mr. Millar, and was voted a sum of $50,000 by the legislature of S. Carolina for the invention of the cotton-gin. He subsequently turned his attention to the manufacture of firearms, supplying the Government according to contract from 1798, and ultimately amassing a large fortune at Whitneyville, Connecticut, a flourishing village which rose round his manufactory. He died at New Haven, January 8, 1825.

Whit'ney, William Dwight, born at Northampton, Massachusetts, 9th February 1827, after graduating at Williams College in 1845, held for some time a clerkship in a bank. Having, however, resumed his studies at Yale College (1849), he visited Europe, and at Berlin under Weber, at Tübingen under Roth, made Oriental languages, Sanskrit especially, the object of three years' investigation (1850-53); and returning home by way of Paris, London, and Oxford, became in 1854 professor of Sanskrit in Yale College, and of comparative philology in 1870. He has been besides a member of the American Oriental Society since 1849, its librarian (1855-73), and corresponding secretary since 1857, and was first president of the American Philological Association. W. has done in America what Max Müller has done in England, popularised the science of language; but as a staunch upholder of the *Thesei* theory of Language (q. v.) he has engaged in an unfortunate contest with the great German scholar; unfortunate because the powers of both combatants have lately been wasted on trivial points, where the difference is often less real than verbal. W. is a clear, logical, and suggestive writer; his works include *Language and its Study* (1867; Eng. ed. by R. Morris, 1876), a *German Grammar* (1869), *German Reader* (1873), *Oriental and Linguistic Studies* (2 vols. 1872-74), *The Life and Growth of Language* (1875), *Essentials of English Grammar* (1877), and a *German-English Dictionary* (1877), besides editions of the *Atharva Veda*, *Surya-Siddhânta*, *Tâittirîya-Prâtiçâkhya*, &c., and important contributions to Böhtlingk's *Sanskrit Dictionary*.

Whit'stable, a village in Kent, 58½ miles E. of London by the L. C. D. Railway, and about 6 miles N. of Canterbury (with which it is connected by a branch line), is celebrated on account of its oysters, reckoned the most delicate in the market, and of which one grower alone sends 50,000 bushels annually to London. A parish church, which dates from the 15th c., was restored in 1876. A causeway locally known as the street, seen some little distance off shore at low water, is thought to be a relic of the Romans. W. has breweries, rope-works, boat-building yards, &c. Pop. (1871) 5481.

Whit'sunday. See PENTECOST.

Whit'suntide is the week which follows Pentecost (q. v.) Sunday, or more strictly the Sunday, Monday, and Tuesday of that week.

Whitt'ier, John Greenleaf, an American poet, was born of a Quaker family at Haverhill, Massachusetts, December 17, 1807. He worked upon his father's farm, learning also the trade of shoemaking, and when eighteen years of age began to write verses for the *Haverhill Gazette*. He attended the Haverhill Academy (1827-29), and subsequently edited various abolitionist journals, and was for a time member of the Massachusetts Legislature and secretary of the Anti-Slavery Society. His poetry consists chiefly of fugitive pieces, of which numerous collections have been published. *Mogg Megone*, and *The Bridal of Pennacook*, both Indian legends, were published in 1836 and 1848 respectively. Besides these may be mentioned *Ballads* (1838), *Lays of my Home* (1843), *Voices of Freedom* (1849), *Songs of Labour* (1850), *The Chapel of the Hermits* (1853), *The Panorama* (1856), *Home Ballads* (1860), *In War Time* (1863), *Snow-Bound* (1866), *The Tent on the Beach* (1867), *Among the Hills* (1868), *Miriam* (1870), *The Pennsylvanian Pilgrim* (1872), *Mabel Martin* (1874), and *Hazel Blossoms* (1875), including the poems of his sister, Elizabeth H. W., who died in 1864. He wrote a hymn for the opening of the Philadelphia Exhibition, 1876, and in the same year a complete *Centennial Edition* of his poems was published in Boston. As a poet his characteristics are vigour, simplicity, and picturesqueness, combined with a lofty love of freedom and sense of right. His versification is now and then rather rugged, and his rhymes are apt to be slovenly, but on the whole he has an honourable place among the first half-dozen poets of America. His principal prose works are *Legends of New England* (Hartford 1831); a *Life of J. C. G. Brainerd* (Hartf. 1832); *Justice and Expediency* (Bost. 1833); *The Stranger in Lowell* (1845), *Supernaturalism in New England* (1847), *Leaves from Margaret Smith's Journal* (1849), *Old Portraits and Modern Sketches* (1850), and *Literary Recreations* (1854). His *Poems*, complete up to that date, were published in London in 1874.

Whitt'ington, Sir Richard, born about 1350 at Pauntley, Gloucestershire, in 1370 lost his father, lord of the manor of Pauntley, and coming afoot to London (so runs the nursery tale), became apprentice to a merchant there. How in his flight from the cook's cruelty he was stayed at Highgate by Bow Bells' chime, and how from the sale of his cat in catless Africa he ended by wedding his master's daughter, are household words. Facts not so widely known are that he really was thrice Lord Mayor, in 1397, 1406, and 1419; that he made large loans to Kings Henry IV. and V., and purchased abroad the trousseaux of Princesses Blanche and Philippa (the invoices still exist); and that, dying in 1425, he devoted his estate to the founding of Guildhall and Grey Friars libraries, the rebuilding of Newgate, the repair of St. Bartholomew's, and similar purposes. In his lifetime, too, he shared in the expense of rebuilding the nave of Westminster Abbey, and caused to be compiled a sort of London Directory, the quaint and valuable *Liber Albus* (1419, translated and annotated by Mr. Riley, Lond. 1859). Mr. Lyson, in his *Model Merchant of the Middle Ages* (Lond. 1860), has fully vindicated W.'s historic character, but he probably goes too far in accepting the 'interesting story,' which Riley accounts for thus—that, in the 14th c., the Fr. word *achat*, 'trading,' was in England written and pronounced *acat*, and that to *a cat* of this nature W. owed his wealth. The explanation is ingenious, but the same tale is told in lands the most remote, even in Persia, and does not seem to have attached itself to W.'s name until the close of the 16th c. See a long discussion of the subject in the 2d series of *Notes and Queries*. A Life of W. by F. Rice is announced (1879) to appear in Ward's 'New Plutarch Series.'

Whitt'lesea or **Whitt'lesey**, a decayed town in Cambridgeshire, 6 miles S.S.E. of Peterborough, with a pop. (1871) of 4297. About 5 miles to the S.W. there formerly existed, over what is now a fertile and richly cultivated tract, a shallow lake, called Whittlesea-mere, which was 2 miles long by 1 broad.

Whit'worth, Sir Joseph, Bart., F.R.S., a well-known mechanician, was born at Stockport in 1803. At the Great Exhibition of 1851 he exhibited a number of improved tools and machines; and a few years later turned his attention to the construction of projectiles and firearms of great range and accuracy. In this department he has gained a high reputation; and for his services in perfecting military armaments he was created a baronet in 1869. The same year he founded the Whitworth Scholar-

ships for the encouragement of engineering science. These consist of 30 scholarships of £100 a year each, and tenable for two or three years. In 1878 he received from the University of Edinburgh the degree of LL.D. He has published *Miscellaneous Papers on Practical Subjects; Guns and Steel* (1873).

Whor'tleberry (a corruption of 'myrtle-berry,' the two fruits being much alike) is a name originally applied to *Vaccinium myrtillus*, but is now used with generic application. *Vaccinium* is the type of the sub-order *Vaccinieæ*, of the natural order *Ericaceæ*, and consists of upwards of 100 species of shrubs with alternate, often evergreen leaves; solitary or racemose white or red flowers; calyx tube 4-5 toothed; corolla urceolate or campanulate 4-5 fid; stamens 8-10, epigynous; ovary 4-5 celled; style filiform, with an obtuse stigma; fruit a berry. The distribution is through Europe and temperate and subtropical Asia and America. The common W. or Bilberry (*V. myrtillus*) is a common plant of heaths and copses in the British Isles, ascending to 4200 feet. It produces a dark-blue glaucous berry about the size of a pea, which is used to a considerable extent for preserves and tarts, and it is a favourite food with grouse. It can also be used as a dye, and the whole plant contains quina acid. *V. Vitis idæa* (sometimes called cowberry) is a procumbent shrub of high moorlands, has evergreen box-like leaves, and produces a red acid berry used for jellies and preserves. The leaves of *V. arctostaphylos*, a shrub of the neighbourhood of the Black Sea, and abundant on the flanks of Olympus, are collected and used in lieu of tea, being sold under the name of 'Broussa tea.' Some American species of the genus are called Huckleberry, the best known being *V. corymbosum* (the swamp blueberry), which bears sweetish bluish-black berries, and *V. Pennsylvanicum*, yielding an abundance of berries in colour and taste similar to the above. Several species of W. are grown in gardens as ornamental shrubs.

Whyd'ah, or **Whyd'aw**, the chief port of the West African kingdom of Dahomey, and capital of a province of the same name. It is situated on a large lagoon, two miles inland, and has an extensive trade in palm-oil, ivory, salt, and gold dust. W. was formerly a chief centre of the slave-trade, and had a pop. of 50,000, which has decreased to 12,000 since the abolition of the traffic.

Whyte-Melville, George John, son of a Fifeshire laird, born near St. Andrews in 1821, was educated at Eton, and entering the army at eighteen, retired after ten years' service, having risen to be captain in the Coldstream Guards (1846). On the outbreak, however, of the Crimean War, he joined the cavalry of the Turkish contingent, and during 1855-56 gained the experiences embodied in the *Interpreter* (1858). This was the fourth of some twenty novels, which, whether sporting, historical, or 'costume,' have all a cleverness and dash that make them popular, among them being *Digby Grand* (1853), *General Bounce* (1854), *Kate Coventry* (1856), *Holmby House* (1860), *The Gladiators* (1863), *Cerise* (1865), *Sarchedon* (1871), *Katafelto* (1875), and *Black but Comely* (1879). He who so well described a good run with the hounds, met his death in the Gloucestershire hunting-field, 5th December 1878.

Wich'ern, Johann Heinrich, a German philanthropist and founder of the 'Inner Mission,' born at Hamburg, 21st April 1808, studied first at the *Johanneum* of that city, then as a student of theology at Göttingen and Berlin, received a benefice in his native town, and gave himself up to earnest practical endeavours to improve the condition of the poor, the suffering, and the lost. In the *Rauhes Haus* (founded 1st November 1833) he established an institution for neglected children, with which a training seminary for teachers was also joined. Institutions on a similar plan were shortly afterwards formed throughout Germany and in several other European countries. In September 1848 he succeeded in forming a central union for the 'Inner Mission,' an association which converted into one regular system 'the whole of the activity for the poor, the sick, the fallen, and those strange to religious and moral influences.' In 1856 he was appointed councillor of the Prussian ministry of the interior, and a member of the higher church council. W.'s writings are entirely of a practical character. The chief is *Die Innere Mission der deutsch-evangelischen Kirche* (Hamb. 1849).

Wick (the town on the *wic* (Scand. *vig*) or 'bay'), the county town of Caithness, and the chief seat of the herring fishery in Scotland, on W. Bay, at the influx of W. Water into the North Sea, 161¼ miles of Inverness by rail. It is divided into three parts—W. proper, the oldest part of the town, Louisburgh, and Pulteneytown, on the S. side of the river, the seat of the manufactures, commerce, and fisheries. Two suburban villages are Staxigo and Boathaven. Pulteneytown is open and well built, its streets radiating in different directions from a large central square. It was founded by the British Fisheries Society in 1808. A new harbour is now (1879) being formed at a cost of £120,000, with a depth at the entrance of 30 feet. There are two harbours, not deep enough, however, for large vessels, while during easterly winds the swell in the bay makes the roadstead one of the most dangerous on the E. coast. W. has distilleries, a brewery, steam saw-mills, rope and sail-cloth factories, and an iron-foundry. Boat-building and the manufacture of barrels and netting are actively carried on. During the herring season (July to September) the population is largely increased, and both land and water present an animated spectacle. The gross annual value of herrings exported is from £150,000 to £200,000. Trade has been considerably developed since the opening of the railway (1874) connecting W. and Thurso with the South. Steamboats ply weekly to Kirkwall, Aberdeen, and Granton. In 1878 there entered the port 1248 vessels of 148,749 tons, and cleared 1222 of 136,233 tons; and on December 31 of the same year there belonged to the port 78 vessels of 8090 tons, besides 1101 fishing-boats manned by 1485 hands. W. unites with Kirkwall, Dornoch, Dingwall, Tain, and Cromarty in returning a member to Parliament. Pop. (1871) 8131.

Wick (Old Eng. *weoca*, primarily a 'bunch'), a number of twisted or plaited cotton threads placed in a lamp or candle to lead up by capillary action the oil or other fatty material to be burned. Wicks are treated with borax or ammonic or bismuth salts to render them less combustible, and the necessity for snuffing or removing charred portions of the W. is obviated in several ways, the simplest of which, applied to stearine candles, consists in plaiting the W. flat, so that it curves over as it burns.

Wick'low, a maritime county of the province of Leinster, Ireland, is bounded N. by Dublin, E. by St. George's Channel, S. by Wexford, and W. by Carlow and Kildare. Area 500,178 acres; pop. (1851) 98,978, (1871) 78,697, a decrease due to the emigration of 19,697 persons during 1851-77. With a steep and dangerous sea-board, W. is inland extremely mountainous, having fifteen summits exceeding 2000 feet of elevation, the loftiest of them Lugnaquilla (3039 feet). The wooded glens, the tarns, and torrents with brawling waterfalls make W. singularly picturesque, but its water area is only 1090 acres, and except that the Slaney and Liffey rise within its borders, the Avoca is its only considerable stream. Of granitic formation, W. is richer than most Irish counties in minerals, the yield in 1877 being 16,725 tons of iron pyrites, 1655 tons of lead ore, 6205 oz. of silver, and 2618 tons of copper ore. The climate resembles that of Wexford (q. v.); the soil in the lowlands is fairly fertile. Of 110,932 acres under crops in 1878 (118,002 in 1853) 3979 were in wheat, 24,770 in oats, 1530 in barley, bere, and rye, 11,150 in potatoes, 5886 in turnips, and 61,033 in meadow and clover, while woods and plantations covered 19,169 acres in 1877. The live stock included 12,183 horses and mules, 3532 asses, 77,804 cattle, 199,452 sheep, and 24,555 pigs in 1878, when the rateable valuation was £271,552. The population is mainly agricultural and Catholic, Protestants numbering 15,305 in 1871; and of the total 28·1 were illiterate, though W. had then 186 schools. Arklow, Wicklow, and Bray are the only towns in the county, which returns two members to Parliament. Among its many antiquities the most famous are the 'Seven Churches' of Glendalough, said to have been founded by St. Kevin (6th c.), and including a 'round tower,' 110 feet high.

Wick'low, a market and seaport town of Ireland, the capital of the county of the same name, lies on the estuary of the Vartrey (called 'Brom Lough'), 28¾ miles S.S.E. of Dublin by rail. It has a church with a tower of 1777, a Catholic chapel, Quaker and Wesleyan Methodist meeting-houses, and one weekly newspaper. Chartered in 1614, W. before the union sent two members to the Irish Parliament. Pop. (1871) 3164.

Wic'lif, or **Wyc'liffe** (the name is spelt in a variety of ways), a great English reformer of the 14th c., was born probably at the village of Spresswall, about half a mile from the

manor-house of the family to which he belonged, and not far from Old Richmond in Yorkshire. The date of his birth may be supposed to fall between 1315 and 1320, the year 1324 assigned by Lewis and accepted by several subsequent biographers being too late to tally with other facts in his life. Of his childhood and youth no account has been preserved. He probably came up to Oxford when a mere lad, and he certainly had a remarkable university career; but all details are wanting till 1356, when we find him (if there is not a confusion with another John W.) seneschal of Merton College. In 1361 he was master or warden of Balliol, and though in May of the same year he was appointed rector of Fillingham in Lincoln, the university continued for a long time the main seat of his activity. About four years later, Simon Islip, Archbishop of Canterbury, appointed W. (if this be not again the other Wycliffe) warden of the new foundation of Canterbury Hall, but after Islip's death he was expelled by the monkish members, whose action was sanctioned by papal bull in 1370 and confirmed by royal decree in 1372. Meanwhile W. had become professor (*i.e.*, doctor) of theology. Lechler thinks it not improbable that he was a member of the famous Parliament of 1366, and at any rate he wrote about this time a tractate or dialogue in defence of the national policy towards the Pope. In 1374 he was one of the commissioners sent to Bruges to arrange a concordat, and about the same time he received from the king himself (Edward III.) the rectory of Lutterworth in Leicestershire. With Edward's younger son, John of Gaunt, Duke of Lancaster, he was in special favour; but this very favour was probably the proximate cause of the first hostile action of the clergy. Summoned before Convocation in 1377, he was saved from all danger by the high-handed protection of the Duke of Lancaster and his friends, who made their way into the assembly and rendered all judicial proceeding impossible; and though in the following year a formidable process was instituted against him by direct command of Gregory XI., the papal commissioners were induced by the intercession of the Princess Joanna and the evident sympathy of the citizens to do no more than forbid him further to disseminate his obnoxious doctrines. But in the course of the following years W. grew more and more estranged from the orthodox creed, and his endeavours to propagate his opinions were of wider scope than before. In 1378 the election first of Urban VI. and then of Clement VII. produced a schism in the Church: each pope condemned his rival as antipope, and W. declared that they were both right, and that the papacy was Antichrist. He called in question the doctrine of transubstantiation, and declared that pilgrimages and monastic vows had no authority from Scripture. And his views were accepted by numerous disciples, and disseminated by preachers through the length and breadth of the land. The ecclesiastical authorities endeavoured to suppress the movement by fair means and foul; but though many of its leaders were silenced, the great originator of the whole continued to the end boldly to bear witness to the truth. He died in peace at Lutterworth, on Sylvester's day, 31st December 1384. The importance of his life work may be read in the religious history of Europe during the 15th and 16th centuries. In England the Lollards, as his followers were called, were driven gradually into the background, but their doctrines were taken up on the Continent by Huss, and continued potent in many ways till they were absorbed in the larger wave of the great Reformation. W. was a man of powerful intellect and philosophic subtlety; uniting a fondness for scholastic speculation and argument with a rare power of appealing simply and effectively to common sense. Wit, humour, and sarcasm abound in his pages. It is not probable that the popular view of W.'s character and position will be seriously modified, but it should be known that a less favourable opinion than the one just expressed has been pronounced by many competent critics. He had a way of minimising his heresies when under examination, and of fortifying himself when in danger with the sword of the civil magistrate, or rather of the 'lords temporal,' that shows a prudent but not a heroic temper. Insisting that every priest should imitate the poverty of his Divine Master, he himself was a pluralist for the greater part of his life.

According to Shirley, his Latin works are 96 in number and his English 65. The latter, of which Arnold recognises only 41 as genuine, are for the most part of the pamphlet type; but among the former there are twelve or thirteen large treatises. A great proportion of the whole are still in MS. It is enough to mention his *Trialogus*, published by Lechler (Oxf. 1869), *De Officio pastorali* (also ed. by Lechler, Leip. 1863), *De Dominio divino* (MSS.), *De Dominio civile* (MS.), and *W.'s Wicket, or a Treatise on the Sacrament* (Oxf. 1612). Thomas Arnold has edited *Select English Works of John W.* (3 vols. Lond. 1869–71). W.'s greatest contribution, however, to English literature was his translation of the New Testament from the Vulgate, which is nearly as remarkable in point of language as the later version of Tyndale. The first edition was printed by Lewis (Lond. 1731). The best edition is Forshall and Madden's *The Holy Bible .... by J. W. and his Followers* (4 vols. Oxf. 1850). See the Rev. Dr. Shirley's *Fasciculi Zizaniorum Magistri Johannis Wyclif* (published 1858 by the Master of the Rolls), the Lives of W. by Lewis (Oxf. 1820), Tytler (Edinb. 1826), Vaughan (Lond. 1828 and 1853), and Lechler (Leip. 1873; Eng. trans., with 'additional notes' by Professor Lorimer, D.D. (Lond. 1878).

Widd'in, a town and fortress of Bulgaria, on the right bank of the Danube, opposite the village of Kalafat, 18½ miles from the Servian frontier, and 130 miles E.S.E. of Belgrade. It is the seat of a Greek bishop, and has an important citadel greatly strengthened since 1853–54, built on a low hill, and surrounded with a double circumvallation with four gates to the landside and five to the river. The difficulty of attacking the fortress is greatly increased by the flat, swampy character of the ground. There are in W. 1730 bazaar-booths, 3 barracks, and 2 hospitals. It manufactures gold and silver filigree and saddles, and has considerable fishery, and trade in rock-salt, corn, wine, and agricultural products. The merchants are principally Jews and Bulgarians. Pop. 25,000–30,000 (the majority Mohammedans). W. is the *Bononia* of the Romans. In 1801 it was the scene of the defeat of the Hospodar Michael Sutsos by Paswan Oglu, and here in October 1853 Omer Pasha began the hostilities against Russia by crossing the Danube and occupying Kalafat, whereafter ensued several battles in the neighbourhood between the Turks and Russians, the chief on the 6th and 19th April 1854. In the war of 1877–78 W. was occupied by 10,000 Turks. Osman Pasha was commandant, and it was from W. he made his unexpected march to Plevna—the scene of his early victories and his heroic defence. By the Berlin Treaty of 13th July 1878 it now belongs to the new principality of Bulgaria.

Wid'geon, or **Wi'geon** (*Mareca*), a species of *Natatorial* birds, allied to the *Anatidæ* or ducks, which migrate southwards to Britain in September and October, leaving that country in their northward flight in April. Some few specimens may breed in the N. of Scotland. The common W. (*M. Penelope*) is about 18 inches in length. The male is white on the top of the head, and chocolate brown on the cheeks and back of the neck. The back is greyish, marked with finely-pencilled lines of black, and the wing-coverts are white, with black tips. The breast is brown, and the under parts white. The tail is long, black, and pointed. The female is of a brown hue. At the close of the breeding season, the tints of the male assimilate to those of the female. The nest is built amid reeds and rushes, and the eggs, which are small, are creamy-white in colour, and from five to eight in number. The flesh of the W. is highly esteemed. An allied species is the American W. (*Moreca Americana*), which attains a length of 22 inches, and is common in winter in the United States. Occasionally it has been found in Britain.

Widow, in law. See GOODS IN COMMUNION, and JUS RELICTÆ.

Wie'demann, Gustav Heinrich, a German physicist, was born October 2, 1826, at Berlin, where he studied medicine and the natural sciences, devoting himself especially to physics, of which he became professor at Basel in 1854. After spending some years at the Polytechnicum in Karlsruhe he was elected professor of physics at Leipzig in 1870, which chair he still (1879) holds. W. has contributed numerous papers on electrical and magnetic subjects to Poggendorff's *Annalen* and other scientific publications, but he is best known as the author of *Die Lehre vom Galvanismus und Elektromagnetismus* (2 vols. 1861, 2d ed. 1872–74), unquestionably the most complete and trustworthy treatise on the subject, not the least valuable feature of which is the system of giving complete references to the various authorities and papers quoted. In 1877 he succeeded Poggendorff as editor of the *Annalen der Physik und Chemie*.

Wie'land, Christoph Martin, one of the greatest of

German authors, was born 5th September 1733, at Oberholzheim, a small village in Swabia, where his father was pastor. He studied at Tübingen (1750–52), lived in the house of the poet Bodmer near Zürich for two years, spent some time in Zürich, then went to Biberach to fill a municipal office (1760), was appointed professor of philosophy at Erfurt (1769), and called (1772) to Weimar by the Duchess Anna Amalie to superintend the education of her two sons. That town was already the intellectual capital of Germany; and when, a few years after, Herder and Goethe went to reside there, it might almost have been called the Athens of Europe. W. spent the rest of a long life on terms of intimate friendship with those illustrious men whom a liberal and enlightened policy had collected at Weimar. He died 20th January 1813. W. was a very voluminous writer. His literary activity falls naturally into three periods—the first ends with his removal to Biberach; the second comprises his residence there and at Erfurt; the third, his residence at Weimar. The chief writings of the first period are *Zwölf moralische Briefe in Versen* (Halle 1752), *Anti-Ovid* (Amsterd. 1752), *Der geprüfte Abraham* (Zür. 1753), *Hymnen* (Zür. 1754), *Empfindungen eines Christen* (Zür. 1755). The characteristics of these works are severe asceticism and strong pietistic feeling, both carried to unnatural excess. To the second period belong *Agathon* (Frank. 1766), *Don Silvio von Rosalva* (Ulm 1764), *Musarion* (Leip. 1768), *Combabus* and *Die Grazien* (Leip. 1770), *Der neue Amadis* (Leip. 1771), and *Der Goldene Spiegel* (Leip. 1772). These show a complete revolution in the thoughts and feelings of the author. This we must ascribe to a natural reaction from the overstrained sentiments of his early years, a disappointment in love, and the influence of new circumstances on an extremely susceptible nature. They are marked by the exaltation of the senses over the mind, a gay Epicureanism, and an easy and occasionally loose morality. To the third period belong *Die Geschichte der Abderiten* (Leip. 1781; trans. by Christmas, 2 vols. Lond. 1861), *Oberon* (Weim. 1781; trans. by Sotheby, 2 vols. 3d ed. Lond. 1826; another ed. 1844); *Auserlesene Gedichte* (Jena 1784–87), containing some of his finest work. In addition, W. edited and wrote for several periodicals, and executed translations of Shakespeare (8 vols. 1762–66), Horace (*Epistles and Satires*, 1782–86), and Lucian (1788). Of W.'s third period it may be remarked that the moral tone is decidedly higher than in the second, while it is also free from the unrestrained extravagance of the first. To this period belongs his greatest work, *Oberon*. The plot of this poem is indeed eminently ridiculous, but the charming manner in which it is developed makes us forgive or forget its absurdities. It comprehends a vast variety of scenes and incidents, and all are treated in a pleasing and lively manner. Human emotions are described with truth and effect. The effect of the collision of counteracting passions, desires, and interests is portrayed with skill and power. Of W. it has been well said that 'once within his magic circle we forget everything else.' His touch, light and airy as it seems, is yet powerful and true; his style is easy, lively, and natural; the sentiments even of his most dangerous writings show that his intellect may sometimes have erred, his heart never did. He is almost the first great name in modern German literature; and when it is remembered who were his successors, it is no stinted measure of praise deliberately to pronounce him worthy of his place. A new edition of W.'s collected writings by Gruber was published at Leipzig (50 vols. 1818–28; new ed. 36 vols., 1839–40), and again (Stuttgart; 36 vols. 1851–56). See also his Life by Gruber (2 vols. Altenb. 1815–16; new ed. 4 vols., Leip. 1827–28); *W.'s Ausgewählte Briefe* (4 vols. Zür. 1815), *Briefe zu Sophie La Roche* (Berl. 1820), Löbell, *Christoph Martin W.* (Brunsw. 1858), Ofterdinger's *W., &c.* (Heidelb. 1877).

Wielicz'ka, a small town in Galicia, Austria, 9 miles S.E. of Cracow by rail, famous for its wonderful salt mines, which have been continuously worked since 1250. They consist of 7 different levels, or storeys, one above the other, connected by intricate passages and flights of steps, and in some places by lofty bridges, measure from E. to W. 12,468 feet, from N. to S. 3117 feet, and reach their greatest depth at 918 feet. The annual production of salt up to 1872 was 37,000 tons, but since that date it has gone down to 30,000 tons, and the number of workmen to 600. Several of the disused galleries have been adorned with statues hewn in the rock-salt, and two chapels have been excavated, in the larger of which the Mass is celebrated annually on July 3. The chapels were injured by the inundation of 1868. Pop. (1869) 6127.

Wiesba'den (Ger. the 'meadow baths'), a town of Prussia, province of Hessen-Nassau, until 1866 capital of the independent duchy of Nassau, lies on the S.W. spurs of the Taunus Mountains, 377 feet above the sea, 6 miles W. of Mainz by rail. It is well built, and contains a large number of splendid hotels. The chief buildings are the Gothic Protestant church (1853–62), a noble edifice with 5 lofty towers, containing colossal marble statues of Christ and the four Evangelists; the Roman Catholic church (1844–49), in the Romanesque style; the English church (1863–65); the new synagogue, in the Oriental style; the Schloss (1837–40); the museum, with a picture-gallery, a collection of antiquities, a natural history collection, and a library of 70,000 vols.; the Pauline palace (1842), in the Moorish style; the government buildings (1842), in the Florentine palatial style; the Greek chapel, erected by the Duke of Nassau as a mausoleum for his first wife, Elizabeth Michailowna; and the Kursaal, the principal resort of visitors, the largest hall of which is 132 feet long, 60 feet wide, and 48 feet high. Connected with the Kursaal by a long iron Trinkhalle is the Kochbrunnen, the principal of the 22 medicinal springs of W. Its waters have a temperature of 156° F. The second spring is that in the garden of the Adler Hôtel, 147° F. W. is one of the most frequented spas in Europe. In 1872 it was visited by upwards of 60,000 patients and travellers. Pop. (1875) 43,674 (14,000 Catholics, 1000 Jews); estimated pop. (1877) 47,500. The springs of W. are spoken of by Pliny as the *Fontes Mattiaci*, and on the Heidenberg, N. of the town, traces of a Roman fortress were discovered in 1838, which seems to have been connected with the town by a wall, the *Heidenmauer* ('heathens' wall'), in the ruins of which votive tablets and inscriptions have been discovered.

Wig. See PERIWIG.

Wig'an (anc. *Wibiggan*, 'holy building'), an important manufacturing, mining, and railway centre in Lancashire, is situated on the river Douglas, 19½ miles E.N.E. of Liverpool by rail. Of its six Anglican churches, the oldest is All Saints' (14th c.; restored 1850), the latest St. Andrew's (1878). For the Catholics, who are strong in W., schools for 800 children were opened in 1874; a church of St. Joseph was built (1877–78); and the foundation-stone of another, St. Patrick's, was laid by Cardinal Manning, 2d Sept. 1878. Among the buildings are the town-hall and public hall, with a concert-room and mechanics' institute; a market-hall and fish-market, erected (1877) at a cost of £14,000; a free library (1877); a hospital, opened by the Prince of Wales (1873), and a grammar-school. A public park of nearly 30 acres was opened in 1878. Cotton-spinning is the staple industry, but there are also iron and brass foundries, cutlery and chemical works, and manufactures of oil-cloths, tarpaulins, &c. The neighbouring collieries have been the scene of many disastrous explosions, one of which in 1877 cost 37 lives, another, in 1878, 200. W. publishes two bi-weekly newspapers, and returns two members to Parliament. Pop. (1877) 39,110; estimated (1878) 44,000. Historically W. is famous as the Earl of Derby's head-quarters in the Great Rebellion (1651), and resting-place of the Young Pretender on his retreat from Derby (1745).

Wight, Isle of, an island in the English Channel, included in Hampshire, from which it is severed by the Solent (q. v.). Area, 93,341 acres; pop. (1871) 66,219. Rhomboidal in form, the island is traversed by a high ridge of swelling chalk-downs, whose loftiest point is Mottiston Down (693 feet), and ending E. in the Culver Cliffs, W. in the Needles headland, the Needles themselves being jagged splinters of the chalk wall that once stretched right across to the Isle of Purbeck. The southern promontory presents a second range, Shanklin, St. Boniface, and St. Catherine Downs (830 feet), and is separated from the central range by the valley of the Medina and Yar, the two chief streams. The beetling cliffs, honeycombed by the sea and gashed by the 'chines' or water-gullies, exhibit in all their fulness the manifold strata that render the island a favourite field for the geologist. Northward from the central chalk ridge, with its nearly vertical strata, are seen in regular succession the Lower, Middle, and Upper Eocene, composed mainly of fresh-water beds interstratified with a few marine beds, while southward from the same are the older members of the Cretaceous

system from the Upper Greensand and Gault, through the Lower Greensand to the underlying Weald clay with its Saurian remains and submerged forests. The stiff clay to the N. of the chalk-ridge pasture-lands grows noble oaks, but is not so well suited for tillage as the rich red loam of the southern half. The mildness of the climate has long attracted consumptive patients, for the poorer class of whom a National Consumption Hospital was founded at Ventnor in 1872. Hundreds of other visitors are yearly drawn by the natural charms of 'that beautiful island, which,' said Sir Walter Scott, 'he who has once seen never forgets;' and Ryde and Cowes are important yachting centres. The latter is also the chief port of the island, being entered (1878) by 19,296 vessels of 1,199,094 tons, and cleared by 18,939 of 1,195,538 tons—chiefly yachts. In 1877 its imports amounted to £11,882, its exports (chiefly grain and wool) to £942. The island contains (1879) 25½ miles of railway; and steamers ply constantly between Ryde and Southampton, Yarmouth and Lymington. The churches of the island are generally more picturesque than architecturally beautiful, but Yaverland, Wootton, Northwood, and Shalfleet retain fragments of Norman work. Carisbrooke Castle, with its grand entrance gateway, is surpassed by few English military ruins; the scanty remains of the Cistercian abbey of Quarr (1132), Osborne, the marine residence of the Queen, and Farringford, for many years the Laureate's home, deserve a notice, as also do the numerous gabled, grey-stone manor-houses. The island, which up to the Reform Bill returned six members, now returns only two, one for itself and one for Ryde.

Doubtfully identified with the *Iktis* of Greek and *Vecta* or *Vectis* of Roman writers, the I. of W. preserves numerous traces of its first inhabitants, the Celtæ and Belgæ—the Longstone *menhir*, innumerable barrows, and the bowl-shaped depressions called 'British villages.' The Roman conquest under Vespasian (43 A.D.) is only recorded by a solitary villa, lately discovered at Carisbrooke; but the Old English, or rather Jutish, cemeteries have yielded many valuable finds. The Jutish occupation dates from 530, when Cerdic of Wessex mastered the island; in 661 it was wrested from Wessex by Wulfhere of Mercia, who transferred it to Ethelwald, the South Saxon king. This 'fierce catechumen' doomed the whole pagan population to extermination, but St. Wilfrith (q. v.), claiming a fourth part as Christ's heritage, founded the first Christian church in W. Danish invasions make up the history of the next three centuries; after the Conquest the lordship of this perilous outpost was granted to William FitzOsbern. On the rebellion of Fitz Osbern's son it was transferred by Henry I. to the De Redvers family, whose last descendant, the Countess of Albemarle, sold it to Edward I. (1293). In the French wars the island suffered grievously, and the flower of its manhood fell with the last of its lords, Sir Edward Woodville, in the defeat of St. Aubin's (1488); and though it so far recovered as to be able to take an active part in the repulse of François I.'s armada (1545), yet its condition under Elizabeth is pictured as deplorable. With the captivity of Charles I. in Carisbrooke Castle (1647-48) the history of the island closes; but one may well recall its memories of Nicholas Udall, Alexander Ross, Dr. Hooke, Bishop Ken, Legh Richmond, Dean Hook, John Sterling, and its greatest worthy of all, Dr. Thomas Arnold of Rugby. See Sir Richard Worsley, *The History of the I. of W.* (Lond. 1781); the *Quarterly Review* for July 1874; and Adams, *I. of W.* (Edinb. 1877).

Wig'ton ('holy town'), a town of Cumberland, England, 11 miles W.S.W. of Carlisle by rail. There is a parish church of 1788, and four chapels. W. manufactures calicoes and ginghams, and there is some tanning and brewing. The district is mainly agricultural. Pop. (1871) 3425.

Wig'town (the 'town on the *wic*' or bay), the capital of the county of Wigtown, situated on W. Bay, near the mouth of the Bladenoch Water, 58 miles W.S.W. of Dumfries by rail. It consists mainly of one broad street, having in the centre an enclosed square, on the E. side of which is the New Court House, erected 1862-63, the finest building in the town. The parish church, a fine Gothic structure, was built in 1852. On the Windyhill, near the town, is a monument to the 'Wigtown Martyrs,' who were drowned in the Bladenoch in 1685. The harbour accommodates vessels of 300 tons. In 1878 there entered it 807 vessels of 50,427 tons, and cleared 783 of 48,167 tons. The number of registered fishing-boats was 21 of 99 tons. Pop. (1871) 1859.

Wig'townshire, the most southerly county of Scotland, forming the western half of the ancient province of Galloway (q. v.), and bounded N. by Ayrshire, E. by Kirkcudbright and the Solway Firth, S. by the Irish Sea, and W. by the North Channel. Area 327,906 acres; pop. (1871) 38,602. The county is deeply intersected by two arms of the sea, Luce Bay on the S. and Loch Ryan (q. v.) on the N., which, approaching within 6 miles of each other, divide W. into two unequal portions, the western, a peninsula 28 miles long by 1 to 6 miles wide, called the Rhinns of Galloway—its northern extremity being Corsewall Point and its southern the Mull of Galloway—connected with the eastern by a flat isthmus. Between Luce Bay and Wigtown Bay is a broad triangular peninsula, forming the district popularly known as the Machars, while the remaining part of the county N. of the Machars and between Loch Ryan and Kirkcudbright is called the Moors. The chief range of hills, a spur from the Lowthers, runs from E. to W. along the N., forming the watershed between Ayrshire and W. Its highest points are Craigairie Fell (1000 feet), Benbake (1000 feet), and Miltonise Fell (970 feet). Three low ranges run S.E., S., and S.W. The highest point in the Rhinns is Cairnpiot Fell (593 feet). The chief rivers are the Cree and the Bladenoch, with its tributary the Tarff, flowing to Wigtown Bay; and the Luce with its affluent the Cross Water, and Piltanton from the Rhinns, emptying into Luce Bay. A striking feature in the water-system of W. is the great number of small lochs and expanses of boggy ground called 'flows.' About ⅛ of the surface is occupied with moor, almost entirely unproductive. Though the soil is nowhere very fertile, excellent crops are obtained under a careful system of farming. Most of the farms are dairy-farms, and the export of cheese is the chief source of wealth in W. In 1878 there were under oats, 32,539 acres; wheat, 2658 acres; barley, 2512 acres; turnips, 16,253 acres; grasses under rotation, 52,437 acres; permanent pasture, 36,201 acres. In the same year there were within the county 5792 horses, 40,401 cattle, 131,030 sheep, and 9491 pigs. The chief towns and villages in W. are Wigtown, Stranraer, Newton-Stewart, Whithorn, Glenluce, Portpatrick, Drumore, Newluce, Lochans, and Kirkcolm. The valued rent in 1674 was £67,607 Scots, or £5634; in 1877-78, £248,113. See M'Ilwraith's *Guide to Wigtownshire* (Stranraer 1876).

Wil'berforce, William, was born at Hull, August 24, 1759, of an old and wealthy Yorkshire stock. Between the ages of nine and twelve he lived with an extremely religious aunt at Wimbledon, and here the seeds of the piety and earnestness he subsequently developed were probably sown. On his removal to a school in Yorkshire, however, he seems to have forgotten the religious impressions he had received, though already his mind had been turned to the question to which he afterwards devoted his life, as is proved by a letter 'on the odious traffic in human flesh' which he wrote while yet at school. At the age of seventeen he entered St. John's College, Cambridge, and fell at first among a wild and 'licentious set of men,' whom he deserted in the course of a year and devoted himself to a higher society, forming the acquaintance of Pitt, whose intimate friend he afterwards became. He devoted himself principally to classics, and graduated with credit. Coming into a large fortune on his majority, he determined to devote himself to a public career, and was returned to Parliament for the borough of Hull in 1780. He now plunged into the vortex of London life, but soon withdrew from it, as he had done in Cambridge. The position he occupied in Parliament was independent, but he always maintained his friendship for and sympathy with Pitt. His powers as an orator were meanwhile developing themselves, and in 1784 he did good service to Pitt's ministry by carrying the county of York unopposed, and so setting an example to other constituencies. In this and the following year his religious convictions were revived, deepened, and strengthened, principally through the influence of Milner, the Dean of Carlisle, with whom he travelled on the Continent. His health, never robust, began to give way seriously soon after his return, but he nevertheless was active in the foundation of an Association for the Discouragement of Vice, and commenced earnestly his great agitation against the slave-trade. The battle was fought by himself in the House, and by Clarkson (q. v.) in the country. He introduced the bill and opened the debate on May 12, 1789, and was of course vehemently opposed, though Burke, Pitt, and Fox all supported him. It was not till 1804

that the bill passed the Commons; then it was lost in the Lords; lost again next year in the Commons, and not carried through both Houses till 1807. The slave-trade crushed, W. did not abandon his exertions in the cause of humanity, and the agitation against slavery as an institution was at once commenced, as well as strenuous efforts to put down the slave-trade abroad. He also occupied himself with many minor philanthropic schemes. Compelled by declining health to retire from Parliament in 1825, he handed over the conduct of the anti-slavery cause to Sir T. Fowell Buxton, and withdrew to his estate at Highwood, near London. Pecuniary losses compelled him to relinquish this residence in 1831, and from then until his death he lived principally in Kent and the Isle of Wight. Three days before his death the bill for the abolition of slavery passed its second reading in the House of Commons, and he thanked God that he had lived to see England spend £20,000,000 in such a cause. He died in London, July 29, 1833, and was buried in Westminster Abbey. His *Practical View of the Prevailing Religious System, contrasted with Real Christianity*, published in 1797, was at one time very popular, 7500 copies being sold in six months, while it was translated into several foreign languages. See his *Life* by his two sons, Robert Isaac and Samuel (5 vols. Lond. 1838; revised and condensed 1868).—**Robert Isaac W.**, second son of the preceding, was born at Clapham, December 19, 1802, took orders in the English Church, became archdeacon of the East Riding of York, was author of numerous theological works, and (as did two of his brothers) went over to the Roman Catholic Church in 1854. He died at Albano, Italy, 4th February 1857.—**Samuel W.**, brother of the preceding, was born at Clapham, 7th September 1805, entered the English Church, became Canon of Winchester in 1840, was Bampton lecturer in 1841, became Dean of Westminster in 1845, Bishop of Oxford in the same year, and Bishop of Winchester in 1869. He was noted as an orator in the House of Lords, and was author of *Agathos* (Lond. 1840), *The Rocky Island* (Lond. 1840), *History of the Episcopal Church in America* (Lond. 1844), *Heroes of Hebrew History* (Lond. 1870), *Essays, contributed to the Quarterly Review* (Lond. 1874), as well as numerous sermons and other theological works. He was killed by a fall from his horse, near Dorking, 19th July 1873. See his Life, edited by Canon Ashwell (Lond. 1879).

Wild'bad, a favourite watering-place of Würtemberg, in the beautiful pine-clad valley of the Enz, a tributary of the Neckar, 28 miles W. of Stuttgart by rail. W.'s celebrity depends wholly on the warm alkaline springs (94°-107° F.) which rise within the very baths, and are visited annually by about 5000 rheumatic patients, who bathe for the most part in large companies, as at Leuk. The only buildings of importance are hotels. Pop. (1875) 3236. See Reny, *Das W. und seine Umgebungen* (Wildb. 1876).

Wil'derness, Battles of the, in the American Civil War, the name conferred on a series of desperate actions in Virginia between the Federals under Meade and Grant, and the Confederates under Lee, May 5-31, 1864. Commencing in the 'Wilderness' proper, a swampy expanse of brushwood to the S. of the Rapidan, the contest was renewed at Spottsylvania and on the bank of the North Anna, and ended in the Federals' repulse at Cold Harbour in their attempt to enter Richmond. The Federal loss was officially stated at 41,398, including 33,948 killed and wounded; that of the Confederates was certainly less.

Wild Fowl, the name applied to birds of various species, which are pursued as game, but restricted by some authorities to birds belonging to the *Grallatorial* and *Natatorial* orders—in other words, to the waders and swimmers. *Wild-fowling* is a favourite British sport, involving in its exercise care, ingenuity, cunning, and even danger. W. F. may be approached with a view to their capture or destruction in various ways. In 'fowling' proper, the *decoy-pond* is perhaps the best-known means for the capture of W. F. in a living state. This pond is constructed in a secluded place, well sheltered by trees, and with a plentiful supply of reeds and sedges. From this pond *pipes* or narrow passages are led, these passages attaining each a length of from 60 to 80 yards, and gradually narrowing towards its termination. Above, the pipe is bridged and covered by a light network, and at its termination it ends in a *tunnel net*, which is, as a rule, carried out on to the land. *Decoy-ducks*, which come to be fed at the call of the attendants, are used to entice their wild neighbours into the pipe; but the *decoy-dog* is perhaps a more valuable ally of the fowler. This dog is named a 'piper.' It is of a small breed, and indulges in playful gambols by the side of the pipe, appearing now and then in advance of the fowl, which, led by curiosity, swims onwards towards the dog, and is thus drawn towards the terminal net. The dog preserves a perfect silence during its manœuvres. The basins named *flight-ponds* consist of sheets of water of limited extent, guarded by nets so placed as to entrap such birds as the Pochard (q. v.) as they rise from the water. W. F. are also captured by shooting from *punts* and *shooting-boats*, great care being necessary in approaching the haunts of the birds; and the *stalking-horse*, still used in some parts of England, is also employed; the body of the horse—which requires special training for its work—being used to conceal the sportsman from the game.

Wild-Fowl Preservation.—The Act 39 and 40 Vict. c. 29 imposes a penalty of £1, with costs of conviction, on any one who intentionally kills, or takes, or exposes for sale, between the 15th of February and 10th of June, any of the different species—Avocet, curlew, dotterell, dunlin, godwit, greenshank, lapwing, mallard, oxbird, peewit, phalarope, plover, plover's-page, pochard, purre, redshank, reeve or ruff, sanderling, sand-grouse, sandpiper, sea-lark, shoveller, snipe, spoonbill, stint, stone-curlew, stonehatch, summer-snipe, teal kick-knee, whaup, whimbre, widgeon, wild-duck, and wild-goose.

Wil'frith, St., born in Northumbria in 634, studied at Lindisfarn, and in his twentieth year repaired to Rome to obtain a decision as to the due season for celebrating Easter (q. v.). On his homeward voyage he formed a friendship with Delfinus of Lyon, whence after three years' stay he returned to England in time to found a monastery at Ripon (664), and as a priest to take part in the famous Council of Streoneshalh or Whitby (q. v.). Here against Colman he triumphantly pleaded St. Peter's claims to obedience as paramount to those of St. Columba, and Oswiu, king of Northumbria, deciding in his favour, conferred on him the vacant bishopric of York. Opposed by St. Chad, he did not, however, obtain possession of the see till 669; from 670 his strife for supremacy began with Ecgfrith, the new Northumbrian king. It ended in his deposition, his visit to Rome for redress, and an incidental mission to the heathen Frisians, thousands of whom are said to have been brought to Christianity by W.'s sermons in their common Low German tongue. He came back with a papal decree in his favour, but soon found himself lodged in Ecgfrith's prison; laboured awhile, on his escape, among the pagans of the Weald of Sussex and the Isle of Wight; then, after a temporary triumph, delusive hopes of succeeding Theodore of Tarsus in the primacy, and a second great council (692), was again deposed and excommunicated, and again took flight to Rome. He tarried there till 705, but ended his stormy career at Oundle monastery in Northamptonshire, April 24, 709.

Wil'helm I. (Friedrich Ludwig W.), King of Prussia and Emperor of the Germans, is the second son of Friedrich Wilhelm III. of Prussia, and was born March 22, 1797. He early entered the army, and took part in the campaigns of 1813-14. The accession of his brother Friedrich Wilhelm IV. (1840) gave W. the governorship of Pommern, and in 1847 he entered the United Landtag, which his brother had so tardily granted; but his absolutist principles were obnoxious to the people, and he fled to England on the troubles of 1848. He re-entered the Diet the following June, but mixed little in its political struggles, contenting himself with suppressing by force of arms a rising in Baden in favour of a constitutional government. The illness of the king unfitting him for governing, W. was appointed regent October 9, 1858, till the death of the former brought him to the throne, October 18, 1861. His first care was the better organisation of the Prussian army, and this involved him in a conflict with the Liberal Chambers, which would not sanction the increased expenditure required for the scheme. W. now appointed as his prime minister and minister for foreign affairs, Otto von Bismarck-Schönhausen, and in the personality of the great minister, W. and Prussian history itself have been merged. Bismarck took up the king's plans and ideas, and carried them through with his energy of character and iron will. A contemptuous dissolution of the Chambers removed obstacles to the army scheme, and Bismarck skilfully met the disaffection at home by turning attention to the Danish war. The close

of this war (1864) made it clear that a struggle was imminent between Austria and Prussia for supremacy in the German States, and Bismarck declared for a settlement of 'blood and iron.' The people regarded it as a 'war of brothers,' and petitions from all sides were presented to W. in favour of peace. But the obstinacy of Austria destroyed such hopes, and hostilities began June 7, 1866. On July 2, W. took supreme command of the Prussian army, and the next day the Austrians suffered the great and decisive defeat of Königgrätz. W. now returned to Berlin, and a newly-elected House of Representatives forgave all unconstitutional conduct in the enthusiasm of victory. North Germany was now led by Prussia; W. only required to bring in the Southern States to form the German Empire. They were wavering, when the declaration of war by France (July 15, 1870) decided them to throw in their lot with Prussia. W again assumed the supreme command of his armies, which included the forces of the South German princes, and following in the wake of their successes, he received Napoleon's sword at Sedan, September 2, and fixed his headquarters at Versailles, October 5. The common sympathies generated by the war had meanwhile been drawing the southern and northern states of Germany closer, and treaties were signed in November 1870 between the Northern Confederation and Hessen-Baden, Bavaria, Würtemberg in favour of a German Confederation, whose president should be Emperor of the Germans. As the result of these, King W. was proclaimed Emperor, January 18, 1871, in the Hall of Mirrors at Versailles. W. and Bismarck had now attained their great objects abroad, the 'unity, independence, and liberty of Germany.' They have since turned to internal questions—Ultramontanism, Education, Socialism. Bismarck's contempt for public opinion has renewed disaffection; the Prince's life has been threatened, and in 1878 two attempts were made to assassinate the Emperor—by Hœdel on May 11, and on June 2 by Dr. Nobiling. In the latter W. was severely wounded, and great sympathy and affection was expressed for him by the people, who acknowledge his unselfish and untiring efforts on their behalf, and are proud of him as the restorer of the German Empire, and who endure, on these accounts, much at his and Prince Bismarck's hands. W. married Marie Luise Auguste Katharine of Sachsen-Weimar (June 11, 1829), and has by her, Friedrich, Crown Prince, and Luise Marie Elizabeth, married to the Grand-Duke Friedrich of Baden. Interesting glimpses of the Emperor are to be had in Prince Bismarck's *Letters* (trans. by Maxse, Lond. 1878). See also Klaczko's *Two Chancellors* (Lond. 1876), and Schmidt and Otto's *Kaiser W. und seine Zeit* (2d ed. 2 vols. Leip 1878).

Wil'helmshöhe. See Kassel.

Wil'helmshaven, a town belonging to the Prussian Landdrostei of Aurich, but surrounded by the Oldenburg territory, lies on the Jahde Bay, 32¾ miles N. of Oldenburg by rail. It has one Evangelical and one Catholic church. W. is the chief war-harbour of Germany on the North Sea. Pop. (1875) 10,158.

Wilkes, Charles, an American naval commander and discoverer, was born at New York in 1801, entered the U.S. navy as midshipman (January 1, 1818), and rose gradually to the rank of rear-admiral, which he attained in 1866. Between 1838 and 1842 he conducted an expedition, organised in the United States, for the exploration of the Southern and Pacific Oceans, a report of which he subsequently published, along with a detailed volume on the meteorological data accumulated. In 1861 he signalised himself by the forcible abstraction from the British mail-steamer *Trent* of two Commissioners to Europe from the Confederate States, for which act, however, his government had subsequently to make amends. The London Geographical Society awarded W. their gold medal in 1848. He died at Washington, February 8, 1877.

Wilkes, John, one of the most notable political figures of the close of last century, was the son of a wealthy distiller in Clerkenwell, where he was born 17th October 1727. He was educated chiefly at the University of Leyden. In 1749 he married a Miss Mead, an heiress, ten years older than himself, from whom, after the birth of a daughter, he was separated, with a scandal very damaging to his character. Settling in Buckinghamshire, he became High Sheriff of the county, and in 1757 was returned to Parliament for the borough of Aylesbury. In June 1762 he commenced his famous weekly paper, the *North Briton*, in which, with the assistance, it is said, of Churchill the satirist and Lord Temple, he attacked and overthrew Lord Bute's ministry. Greville's ministry, which followed, fared no better at his hands, until, on April 23, 1763, he published a violent attack upon the King, accusing him of having uttered a lie from the throne. He was arrested on a 'general warrant,' thrown into the Tower, and had his papers seized; while the seditious *North Briton* (No. 45) was, by the order of the House of Commons, burned by the common hangman. He was soon released, however, it being decided that general warrants were 'unconstitutional, illegal, and absolutely void,' and he was awarded £1000 damages in a suit against the Under-Secretary of State for the seizure of his papers. In the beginning of the next year he was expelled from the House of Commons, and was tried before Lord Mansfield, at the instance of the House of Peers, for republishing No. 45 of the *North Briton*, and for printing and privately circulating an obscene poem called *An Essay on Woman*. On both charges he was found guilty, and having fled to France, was outlawed. It was proved, however, that his accusers had obtained a copy of the poem by dishonourable means, and his popularity became greater than ever. Returning to England in 1768, he was elected to Parliament by the county of Middlesex, arrested on account of his outlawry, rescued by the mob, but ultimately imprisoned of his own free will. On the assembling of Parliament, a mob gathered outside the prison to conduct him to the House, and was only dispersed by the military after some bloodshed. The sentence of outlawry was reversed, but he was a second time expelled from the House of Commons for having charged Lord Weymouth with 'planning the horrid massacre' by which the riot was put down. Again and again he was returned to Parliament for Middlesex, though the House had declared him incapable of sitting in it, and ultimately his opponent, Colonel Luttrell, took his seat, though he had only polled a few votes, on the ground that the votes polled for W. were illegal. This contest made him the popular idol, and though he was now in prison for libel, rich presents were sent him, and £20,000 were subscribed to pay his debts. Liberated in April 1770, he was elected Alderman of the City of London, and was several times summoned to answer at the bar of the House of Commons for his conduct in that office, but always refused to appear except as member for Middlesex. In 1774 he became Lord Mayor, and being once more elected for Middlesex, took his seat in the House, though he did not until 1782 procure the expunging from the records of the resolutions of expulsion. He became in 1779 Chamberlain of the City of London, which post he held until his death, in London, 27th December 1797. He edited Catullus (1788) and Theophrastus (1790), and his *Letters to his Daughter* were published in 1804. He is said to have been the ugliest man of his day, but was a bright wit and had a rare gift of popular oratory. See Almon's *Correspondence of J. W., with a Memoir* (Lond. 1805, 5 vols.), Watson's *Biographies of W. and Cobbett* (Lond. 1870), and W. Fraser Rae's *W., Sheridan, and Fox* (Lond. 1871).

Wilk'ie, Sir David, the greatest of Scottish genre painters, was born at Cults, in Fifeshire, 18th November 1785. The son of a minister, he was intended for the Church, but his love of drawing overcame all opposition, and in 1799 he was placed in the Trustees' Academy, Edinburgh, where he was a diligent student under John Graham for four years. Returning home, he painted 'Pitlassie Fair,' which he sold for £25. The work, which is small in size, is characteristically full of figures and incidents, but in its redness and harshness gives little promise of the artist's future excellence in colour. In May 1805 W. sailed from Leith to London, and there secured admission to the schools of the Royal Academy. At the Academy's Exhibition of 1806 his 'Village Politicians' took the public interest by storm, with its air of local truth, force of character, and gleeful originality. The works which followed are known, at least through engravings, to all the world, comprising such masterpieces as 'The Blind Fiddler' (1807), 'Card-Players' (1808), 'Rent Day' (1809), 'Jew's Harp,' 'Blind Man's Buff' (1812), 'Village Festival' (1813), 'Distraining for Rent' (1815), 'Penny Wedding' (1820), 'Reading the Will' (1821). The 'Rent Day' brought him 300 guineas, and gained him his election as A.R.A. Two years later he was made an R.A., and in 1814, along with Haydon, made his first visit to the Continent, spending some six weeks in France. In 1821-22

he painted for the Duke of Wellington the famous semi-historical work, 'Chelsea Pensioners Reading the Gazette of Waterloo,' for which he received 1200 guineas. On commission for George IV. he produced in 1823 'The Parish Beadle,' widely regarded as the culmination of his early and truly great style. His promotion to the rank of King's Limner, on the death of Raeburn, was signalised by his picture of 'George IV. entering Holyrood.' Meanwhile his health, never robust, became affected by domestic troubles and pecuniary losses; and a long tour on the Continent (1825-28) left him an imitator, bold and successful, but still an imitator, of the old masters. Before returning he visited Madrid, and, fired with enthusiasm by the works of Velasquez, he succeeded, in 'The Guerilla Council of War,' 'Maid of Saragossa,' and 'Confessional,' in approaching the Spanish effect and tone. The public was disagreeably surprised by this change in W., and perhaps there is reason to regret that a manner more ambitious, touched as it is with many graces, should have taken the place of his character sketches and domestic stories on which the fame of the painter rests. On the death of Lawrence, W. was nominated Painter-in-Ordinary, and in 1836 he received the honour of knighthood. After painting several portraits, and advancing a long-delayed work, 'John Knox Preaching,' he suddenly started for the East to seek new fields of art in the localities of sacred narrative. But on his return, while at Malta, he was attacked by sudden illness, and died off Gibraltar, 1st June 1841. On the same evening his body was committed to the deep, but, as an appropriate memorial, his statue by S. Joseph was placed in the vestibule of the National Gallery. The art which will always entitle W. to a higher place in the English school, while it deals with common incidents and familiar phases of character, is ennobled by the sentiment of pathos, or redeemed from vulgarity by humour. A genial sage, original moralist, and the great art-master of rural character and manners, W. as a painter has a close affinity with the Dutch school, subordinating colour as he does to careful finish and the dainty manipulation of details. The chief of his early works were engraved in line by Raimbach & Burnet, and in 1842 some 130 of his works were exhibited with the old masters at the British Institution. See *Life* by A. Cunningham (Lond. 1844).

Wilkinson, Sir John Gardner, born at Hardendale, Westmoreland, 5th October 1797, studied at Harrow and Exeter College, Oxford, and then during a twelve years' residence in Egypt, which he visited for his health, devoted himself to a laborious investigation of the antiquities of that country, whose first-fruits was *The Topography of Thebes and General View of Egypt* (1835). This was followed by *The Manners and Customs of the Ancient Egyptians* (5 vols. 1837-41; new ed. by Dr. Birch, 3 vols. 1878), a work that, illustrated by the author's beautiful drawings, remains a standard authority on Egyptology; and later publications were *Modern Egypt and Thebes* (2 vols. 1844), *Architecture of Ancient Egypt* (1860), *Popular Account of the Ancient Egyptians* (1854; new ed. 1871), *Egypt in the Time of the Pharaohs* (1857), and numerous papers read before the Geographical Society. He further assisted Rawlinson in the Egyptian portion of his translation of Herodotus, in *Dalmatia and Montenegro* (2 vols. 1848) described a visit to the Slavonic Provinces, and wrote *On Colour and the Necessity for a General Diffusion of Taste* (1858). Knighted in 1839, he died at Llandovery, Caermarthenshire, 29th October 1875.

Will is in law an act by which a man disposes of his property after his death. Formerly a verbal or *nuncupative* W. was, under certain circumstances, valid regarding personal property; but by 1 Vict. cap. 26 all verbal wills subsequent to 31st December 1837 are void, except those of soldiers and sailors on service. A W. in England must be attested by two witnesses; but in Scotch law see HOLOGRAPH; and regarding real estate in England see DEVISE. A legacy to an attesting witness, or his or her wife or husband, is void. Marriage revokes a W. made previous to it, the only other means of revocation being destruction of the writing by the testator, or by his direction; or by execution of a new will at variance with the previous one. The following classes cannot make a W.: infants (see AGE), idiots, lunatics, persons in dotage, felons, and outlaws. A W. made under intoxication is void, unless subsequently acquiesced in. A married woman cannot make a W. without consent of her husband, unless she is legally freed from him; or unless by provision under marriage contract. By the Wills Act, which does not apply to Scotland, all property, real and personal, may be disposed of by W. in the same manner; and the owner of real estate can leave it to whom he pleases. It is a common error to suppose that *a shilling*, or other sum real or nominal, must be left to the heir-at-law effectually to disinherit him. A W. made under the influence of importunity, or coercion, or fraud, is void. Any intention of the testator will be given effect to, unless frivolous or contrary to law (see LEGACY). Regarding a *codicil*, see that article. Printed forms of wills should not be trusted to. Great care should be taken to identify a legatee. In leaving a legacy to a married woman, trustees should be appointed, or it will fall to her husband. Any one dying without a W. is said to die *intestate* (see INTESTACY). In Scotland, only *movable*, *i.e. personal*, property can be disposed of by W. To dispose of *heritable* or *real* estate after the testator's death, there must be a conveyance in legal form to the disponee, with reservation of the testator's liferent. He usually also reserves power to alter. See Flood's *Elementary Treatise on the Law of Wills* (Lond. 1877).

Will, The, is that power of control which the mind possesses over its own operations. It is frequently spoken of as a distinct faculty; but we should remember that it is the whole mind that wills, for the mind cannot be conceived as a whole divided into parts like the body, but rather as a unity that may act in different directions, and perform various functions. Now it is evident that the mind does not act without a cause—that is to say, there is no act of W. without a motive; but what is the exact relation between them? Does the W. determine the strongest motive, or does the strongest motive determine the W.? In other words, is the W. free? This Hume calls the 'most contentious question of metaphysics, the most contentious science.' But it is more than a mere vain dispute. The most vital problems of human existence and destiny depend upon the answer. The arguments on either side of the question may be thus briefly given.—A. For the freedom of the W. (1) The testimony of consciousness. We have the best and clearest evidence here that can possibly be given us. In the act of deciding we are clearly conscious that we might have decided otherwise, and we believe the same thing when the act is looked at before or after completion. (2) Men recognise that they are responsible for their actions; but responsibility implies a power in the agent to do otherwise. We do not hold a physical force responsible. We may say that it was *the cause* of a given effect; but of a man we say he *ought*, and this implies that he *can*. (3) Punishment is justifiable only on this theory. It is inflicted because out of two possibilities of action the man has chosen the evil one. If the power of choice were absent, then *summum jus, summa injustitia*, all law would be simply unmeaning revenge. (4) How otherwise can we explain what are called the moral sentiments—remorse, shame, commendation of virtuous action, &c.? Any such feelings are inexplicable except on the hypothesis that they are called into action by the contemplation of the conduct of a free W. agent. (5) We may sum up these arguments thus: the course of all human action at once presupposes and proves the theory; and its truth is assumed consciously or unconsciously in every one of our actions as rational and moral agents. B. Against the freedom of the W. The advocates of Determinism bring forward the following arguments in proof of their position:—It is necessary, they affirm, first clearly to understand what the determinist theory really is. It is *not* fatalism, and therefore the term 'Necessitarians' so often applied to them must be set aside as misleading. If I know that a house will be burned to the ground to-morrow, my foreknowledge would on the fatalistic theory make no difference in the result, but on the determinist hypothesis it would supply me with motives urging me to take efficient means to avert the disaster. J. S. Mill puts the theory thus: 'A volition is a moral effect, which follows the corresponding moral causes as certainly and invariably as physical effects follow their physical causes. Whether it *must* do so I acknowledge myself to be entirely ignorant, be the phenomenon moral or physical. All I know is that it always *does*.' In short, (1) we must apply the law of causality to mind just as we apply it in the external world. If we carefully look back on any act, and consider the motives that influenced us at the time, we clearly see that we could not have acted otherwise than we did. If we had, the motives, that is to say the causes, must have been different. (2) As to

punishment, the only proper justification for its infliction is the good of society, and of the criminal himself. We thus supply motives towards well-doing. (3) Responsibility simply means liability to punishment; while (4) the existence of the moral sentiment is explained by the influence on us of education and of the opinion of others—a man will feel shame at the commission of certain acts whether he could have prevented them or not. (5) If the W. has a choice between motives, these must be of unequal force: if it always chooses the most powerful, then determinism is proved; if it always chooses the weaker, that is surely more absurd than to say it acts from no motive at all—a position which is not maintained. If it choose a motive, it must have had a motive for such choice, and so on. Thus we are brought back to the continuous chain of cause and effect operative in external nature.

If we enter the region of metaphysical theology, we find a very great difficulty in regard to free W. It seems directly to collide with Divine sovereignty. From the very conception of Deity, all must be foreordained, and there is no room left for independent human action. This is a real, and to some extent an insoluble, difficulty. Wise theologians have therefore relegated it to the province of faith or belief. From reflection on the foregoing it will be seen how important this question is in ethics, metaphysics, and theology. It has been a question in debate from the earliest period in the history of human thought, and so it will remain a question in debate to the close, for no final or absolutely satisfactory answer can be given to it. The doom of philosophy—to seek and *not* to find—is in no other case felt so fatally as in this, where so many perplexing and profoundly important questions are concerned. A full quotation of authorities, with summation of arguments on both sides, will be found in Calderwood's *Handbook of Moral Philosophy*.

Will'em II. (W. Georg Lodewijk), King of the Netherlands, Grand Duke of Luxembourg, Duke of Limburg, son of W. I., was born at the Hague, December 6, 1792. The French republican army drove his father from the throne in 1795, and the prince was educated at the military school of Berlin, and at Oxford. In 1811 he joined Wellington's army in the Peninsula as an aide-de-camp. Soon promoted to a colonelship, he was distinguished by great bravery at Ciudad Rodrigo, Salamanca, and Vittoria, and at Badajoz he entered the breach at the head of the storming column. On the return of his father to the throne of the Netherlands, W. received the command of the Dutch army, and took part in the battles of Quatre-Bras and of Waterloo, where he was wounded. On February 26, 1816, he married Anna Paulowna, sister of the Emperor Alexander I. of Russia. In the troubles of 1830, W. acted as mediator between the government and the disaffected; but his acknowledgment of the independence of Belgium caused his recall. He again entered the field on the short and unsuccessful August campaign against Belgium, when the armed intervention of France stopped his progress. W. now withdrew to private life, till the abdication of W. I. brought him to the throne (1840). A struggle followed over reforms which W. would not grant till the French Revolution of 1848 made refusal impossible. The two chambers of the new constitution had hardly met when W. died, March 17, 1849. See *Het Leven van Willem II.*, by J. J. Abink. —**W. III. (W. Alexander Paul Frederik Lodewijk)**, eldest son of the preceding, was born February 19, 1817, educated by private tutors and at the University of Leyden, and succeeded to the crown on the death of his father, March 17, 1849. Ten years previously he had married Sophie, daughter of King Wilhelm of Würtemberg, by whom he has two sons; Willem, born September 4, 1840, and Alexander, born August 25, 1851. His peaceful reign has given opportunity for internal development. A network of railways has covered the country, a canal has been cut through the Isthmus of Holland, which gives easy access to Amsterdam, and the entrance to Rotterdam Harbour improved. By the drainage of Haarlem Lake in 1852, 72 square miles of land, on which a population of 7000 or 8000 people now dwell, was reclaimed from the sea, and the drainage of the Zuyder Zee is now being carried on. W. lost his queen June 3, 1877, and in 1879 married the Princess Emma of Waldeck.

Will'ems, Jan Frans, the 'Father of the Flemings,' was born at Bouchout, near Antwerp, 11th March 1793, and as a lad took part in the Mysteries acted by the Lierre *Rederijkers*. His thoughts were thus turned to poetry, and two years after his entering the office of an Antwerp notary he won a prize for the best poem upon the battle of Friedland and peace of Tilsit (1811). His ode *Aen de Belgen* (1818), hailing the revival of Belgian nationality under Holland's protection, was coldly received by W.'s countrymen, but earned him a post under the Dutch government, while a series of masterly philological works, including *Over de Nederduitsche Taal en Letterkunde* (2 vols. 1819-20), procured him admission to the Academy of Antwerp. Degraded by the new Belgian government of 1830 to a petty office at Encloo, W. laboured there on the Flemish version of *Reynard the Fox* (q. v.), in his edition of it (1834) calling on Flemings to help to preserve their ancient tongue. As archivist of Ghent from 1835 he edited the *Rymkronyk van Jan van Helu* (1836), *Brabantsche Yeesten* (1839-43), &c., and after his death at Ghent, on 14th June 1846, appeared his collection of old Flemish songs, and his *Mengelingen van Vaderlandschen Inhond*. See his Life by Snellaert (Ghent 1847).

Will'emstadt, the capital of Curaçao (q. v.). It stands on the S.W. coast, on St. Anna Bay, and is built in the style of a Dutch town. Pop. 7000.

Will'et (*Symphemia semipalmata*), a species of *Grallatorial* or wading birds, allied to the *Scolopacidæ* or snipes, and inhabiting the New World. They inhabit the northern regions in summer, and migrate southwards in winter. The average length is 15 inches; the general colour greyish brown above and white beneath. The wings are long and powerful, and the toes partially webbed—a feature from which the specific name 'semipalmata' has been derived. Both the flesh and eggs are eaten in America.

Will'iam I. 'the Conqueror,' King of England, was born in 1027. His parents were Robert, surnamed 'the Devil,' Duke of Normandy, and Arletta, the daughter of a tanner at Falaise. When Robert set out on his Jerusalem expedition, his son took his place at the age of seven, and in the following year the young deputy was by his father's death left to face a turbulent nobility alone. The disorder that surrounded him at last becoming open revolt, W. was surprised at his hunting seat at Valognes by the rising of the Bessin and Cotentin districts, but after flight across the Vire routed the rebels at Val de Dunes, 1047. By the influence of Geoffrey Martel, Comte d'Anjou, France, hitherto friendly, became the enemy of Normandy, and in 1054 a battle resulting from this hostility ended at Mortemer in W.'s victory. Four years later he inflicted on France a severer blow, routing its armies on the banks of the Dive. In 1060 Martel died, and both Maine and Brittany fell an easy prey to Norman invasion. W. laid some claim to the throne of England, in spite of his illegitimacy. He traced his descent from Queen Emma, sister of his grandfather, and obtained fealty from Harold, the son of Earl Godwine, when the latter visited the Norman court. But on the death of Eádward the Confessor, Harold was proclaimed king, and in bursts of fury W. levied army and fleet. He landed 60,000 men at Hastings, September 28, 1066. There he awaited Harold, who came from war in the N., and on the 14th of October was fought the battle of Senlac. This fierce contest ending in W.'s victory and Harold's death, the English elected Eádgar Ætheling king. Eádgar, however, quickly yielded his claim, and W. was crowned at Westminster, December 25. The new sovereign at first endeavoured to rule in gentleness, while reserving all power to the Normans. So successful was his usurpation that in a few months he thought it safe to return to Normandy, leaving government in the hands of his brother, Bishop Odo. Troubles soon recalled him, and a terrible change of policy ensued. The king trampled down all opposition, and marching as far N. as the Tees, laid waste all the country from the Humber upwards, killing 100,000 people. English monks, priests, and prelates gave way to Normans, the populace was reduced to serfdom, and the French tongue in the seats of influence and learning silenced the Old English. The iron power of the invaders was too great to be resisted, and such rebels as Morkere, Eádwine, and Hereward sank before the vigilant king, who even carried his conquests into Scotland, forcing it to submit in 1072. A conspiracy formed by his own nobles he quelled in the battle-field, and to a hostile fleet of Danes he gave gold enough to send them home. That these pirates might have no hold on the country, the whole north-east coast was laid bare. Castles were built and garrisoned all over the land, to keep the people

in the strictest subjection. Feudalism extended so far that 60,000 knights were at any moment ready for the royal service. The Norman Conquest was accomplished. An unsuccessful contest in Brittany next engaged the attention of W.; but this ended peacefully in the marriage of his daughter Constance to the Count of Brittany. The Conqueror, in 1053, had married Matilda, daughter of the fifth Earl of Flanders, and one of his sons by this union was in revolt because of a dispute regarding the duchy of Maine. Robert was backed by the young Norman nobility, and by the power of France, and after repeated contests an agreement was come to between father and son through the intervention of Matilda. Returning to England, W. invaded Wales in 1081. The remainder of his life was chiefly spent in Normandy, while Odo retained power in England. Philippe I. of France making an untimely joke on his corpulency and sickness, W. rose from his bed and set the French border in flames. At the burning of Nantes his horse stumbled on the hot embers, and gave its rider a fall which resulted in his death at Rouen, September 9, 1087. W. knew how to rule in these rough times, with sword for sceptre. King of a nation that detested him, with turbulent nobles and rebel sons, surrounded by greedy, powerful neighbours, he was sovereign among them all. He was fierce and cruel, but in his fiercest moments a consummate statesman. Through feudalism he not only secured his power, but civilised the duller English, whose sturdy worth mixed so well at last with Norman elegance and learning. The sway of the Conqueror, if severe, yet rescued the country from a multitude of petty rulers, amidst the squabbles of whom it was sinking into decay. Trade found in him the steadiest protector, and he organised the administration of justice in an efficient and impartial manner. The Domesday Book testifies to his vigorous administration, as did also a Church purged of much impurity and quickened from indolence into life. The primary source of information regarding the Conqueror is the work entitled *Gesta Willelmi* by his chaplain, William of Poitiers. See also Freeman's *History of the Norman Conquest* (5 vols. 1867-76); Stubbs's *Constitutional History* (3 vols. 1874-78); and Green's *Short History of the English People* (1875).—**W. II.**, King of England (surnamed *Rufus*, or 'Red'), second son of the Conqueror, was born in Normandy in 1056. On the death of William, Rufus crossed to England with his father's ring, and Lanfranc's influence set him on the throne. Instantly the barons rose on the side of the elder son Robert; but the English subjects gathered, and under Bishop Wulfstan defeated the western insurgents, while the king marched on Rochester, the garrison of which capitulated. Content among the English changed to discontent when Rufus disregarded his promise to restore the laws of the Confessor; and after the death of Lanfranc (1089) he ceased to govern with justice or moderation. In order to replenish his exhausted coffers he steadily refused to appoint to vacant sees, and appropriated the revenues; so that at his death one archbishopric, four bishoprics, and eleven abbeys lacked pastors. To this and other forms of exaction from the Church W.'s memorable opponent, Archbishop Anselm, offered a stern resistance that greatly mitigated the evil. Part of the funds wrung from the ecclesiastics went towards the completion of the Tower of London and the building of London Bridge. In 1091 W. the Red invaded Normandy, to retaliate Robert's attempt on England; and on Robert's partially submitting, the two brothers attacked the third, Henry, who was driven from his province of Cotentin. Returning to England with Robert, W. defeated the invaders from Wales and Scotland; but, pressing into the latter country, he was only saved by the aid of Eadgar the Ætheling. After a second time defeating a Scotch invading army, W. again attacked his brother Robert, whom he was on the point of subduing when disturbances in Wales called him back. Robert then pledged Normandy to his brother for £10,000 in order to join the First Crusade. A rebellion at Le Mans occurred, and at the news W. threw himself into the first boat at hand, crying 'Kings never drown!' and crossed the Channel. Another raid into Scotland, this time successful, compelled Malcolm to render homage, and the speedy death of that king allowed his superior to place on the throne as a dependant Edgar, the son of Margaret. While hunting in the New Forest he was killed, accidentally or intentionally, by an arrow of Sir Walter Tyrrel, August 2, 1100. Dissolute though he was, W. had great soldierly qualities. See Freeman's *History of the Norman Conquest* (5 vols. 1867-76), and Green's *Short History of the English People* (1875).—**W. III., King of England (William Henry of Nassau, Prince of Orange, Stadtholder of Holland)**, born at the Hague, November 4, 1650, was the son of William II., Prince of Orange, by Mary, daughter of Charles I. He was born to vast pretensions, though his party was for some time kept in check by the influence of Cromwell. The states of Zealand elected him 'first noble,' in virtue of which title he entered the States-General as a deputy. In 1672 the political situation was so far changed that W. was unanimously appointed Captain- and Admiral-General of the United Provinces (February 24), and immediately faced the allied English and French. The allies at last changed their tactics, and offered to erect W. as despotic ruler in his country, but he resisted such proposals. For political reasons W. then married his cousin, the Princess Mary, daughter of the Duke of York; but it was only after several years that this union proved fortunate in a domestic sense. In the following year (1678) the treaty of Nimeguen put an end for a time to the aggressive policy of Louis XIV., and the Orange defender of Protestantism obtained a temporary increase of popularity in England. At the accession of James II. he aided him against Monmouth, but he soon found his interests imperilled by connection with a Catholic king who aimed at absolute monarchy, and Holland became the refuge and resort of Protestant intriguers. The king's conduct at last causing universal discontent, W. was invited to England, and landed at Torbay with 15,000 men, November 5, 1688. The country was his at once, and James fled to France. A Convention was assembled on January 22, 1689, and passed more than a fortnight in arranging a new constitution. In partial submission to the peremptory demands of W., the law-makers departed from their intention of making him owe all his authority to the queen his wife. He was made king, and the reign of William and Mary was inaugurated on a satisfactory basis (February 13). The Scottish Highlanders, however, continued true to James, and of Ireland the deposed monarch had almost entire possession. In 1690 matters were nigh settled by William's victory of the Boyne (July 1), and James again took refuge in France; but the English were checked before the gates of Limerick, and it was reserved for Ginkell to restore peace to Ireland in the following year. Meantime, the death of Dundee had left the Highlanders without a competent leader, and a sullen quiet was brought about in the North, partly by the atrocious massacre of Glencoe (1692). In 1695, the death of Queen Mary diminished her husband's influence, and leaving factious opposition at home, he had to maintain unequal strife with Louis, until the Treaty of Ryswick was brought about by sheer exhaustion on both sides (September 1697). A partition treaty regarding Spain was violated by Louis, who took the throne of that country for his grandson, the Duke of Anjou; and the French king, on the death of James II., acknowledged his son as successor. The English, enraged at this, were making preparations for a powerful invasion, when W. was thrown from his horse while hunting, and died March 8, 1702. His career was one of incessant and strenuous activity, and he carried himself victoriously amidst immense difficulties and numerous discomfitures by a certain cold magnanimity and sullen heroism. The predominant motive of his foreign policy was resistance to the aggressive and tyrannous policy of Louis XIV. To this he was pledged as a Dutch stadtholder, long before he became King of England, and there is no doubt that he accepted the latter dignity not from a vulgar ambition to win a great throne, but to wield a potent weapon in his conflict with French despotism. If, on the one hand, this policy dragged England more thoroughly than before into the circle of European politics, and forced upon her a series of military enterprises not necessary to her welfare, Englishmen, on the other hand, cannot but feel grateful to the ruler who accepted the throne under conditions that secured them a free constitution, with political institutions capable of receiving (as they have received) indefinite improvement without danger of destruction. The sacred principle of toleration both in things civil and in things ecclesiastical was firmly established, though its full bearings and application were not clearly apprehended. Extreme fanatics hated him—Covenanters in the North and High Churchmen in the South—but the great mass of moderate and reasonable Protestants felt that he was a thoroughly practical and inflexibly just sovereign. That he loved, trusted, and advanced his countrymen is not greatly to his discredit. They were loyal to

him, and not disloyal to England. He could not become an Englishman, but he could act like one. His temper was indeed cold, but the nobler passions of man were in him deep and strong. Moreover, he had that stern love of truth, honour, and right that distinguishes a moral hero. Few greater kings have ever ruled in England. See Trevor, *Life and Times of W. III.* (2 vols Lond. 1835–36); Vernon, *Court and Times of W. III.* (3 vols. Lond. 1841); Macaulay, *History of England* (1849–55); and Ranke's *Englische Geschichte vornehmlich im 17 Jarhundert* (6 vols. 1859–67; 4th ed. 1877; Eng. trans. Oxf. Clar. Press 1875).—**W. IV.**, King of Great Britain and Ireland, third son of George III. and Queen Charlotte, was born on August 21, 1765. His education was entrusted to Dr. Magendie, and afterwards to Colonel Bude, till, in 1779, his early likings were gratified, and he entered the navy as midshipman on board the *Prince George*. After seeing active service under Admiral Rodney against the French, Spaniards, and Americans, Prince W. returned home, spent two years on the Continent, and was made a lieutenant in 1785, and a captain in the following year. He now served under Nelson in the W. Indies, but his insubordination, and the difficulty of punishing a prince of the royal blood, practically ended his professional career. In 1789 he was made Duke of Clarence and St. Andrews, and Earl of Munster; in 1801 he had risen to be Admiral of the Fleet; and he still showed great interest in naval affairs in the debates of the House of Lords. Since 1791 he had been living in retirement with a famous actress, Mrs. Jordan, by whom he had a family of ten children. With reluctance he abandoned a twenty years' connection, but political grounds demanded it, and on the 11th July 1818 he married Adelaide, eldest daughter of the Duke of Saxe-Meiningen. The death of the Duke of York (1827) made W. heir-presumptive to the throne, and on the death of George IV. he became king, June 26, 1830. The French Revolution of that year fanned the discontent at home, and the agitation for reform had begun. W. favoured the demand, which was successful (4th June 1832) only on the resignation of the Duke of Wellington. The rest of W.'s reign was taken up by prosecuting reforms in detail, though the king was rather alarmed at the result of the changes. 1833 saw the abolition of slavery, and there followed reforms in the poor laws, in town councils, and in the Irish Church. After a short illness, W. died June 20, 1837. The two children of Queen Adelaide having died in infancy, he was succeeded by his niece Queen Victoria. Devoid of anything like genius, W. was characterised by good sense. He was, as Thackeray said, 'a man,' and his people always loved their 'sailor king.' See Harvey's *Life of Peel* (Lond. 1852), the Duke of Buckingham's *Courts of W. IV. and Victoria* (Lond. 1861); and the *Greville Memoirs* (2d ed. Lond. 1874).

Will'iam the Lyon, King of Scotland, sometimes also called W. the Ruddy and W. the Rough, succeeded his brother, Malcolm IV., in 1165. His surname is supposed to have arisen from the fact that he substituted a lion for the old dragon in the royal arms of Scotland. W. renewed the contest of David and Malcolm IV. with the English kings about Northumberland, and while invading England he was captured at Alnwick Castle, July 13, 1174, as he rode under cover of a mist with a small party of knights. Henry II., who sent him to the castle of Falaise, in Normandy, now pressed hard the claim of English suzerainty on the captive king, and W. was liberated only on a promise of vassalage. This bargain held for fifteen years, till Richard I., needing money for the crusades, revoked the claim on payment of 10,000 merks. The appointment by W. of a bishop of St. Andrews, in opposition to one chosen by the clergy, involved him in a quarrel with the Church, till the death of the Pope brought peace. W. died in 1214, after a reign of forty-nine years. He was the first Scottish king who formed an alliance with France. See Burton's *History of Scotland*, vol. ii.

Will'iam, Prince of Orange, Count of Nassau, and first Stadtholder of the United Netherlands, was born at Dillenburg 16th April 1533. He was the eldest son of Wilhelm, Count of Nassau-Dillenburg, and at the age of eleven inherited from his cousin René, son of his father's elder brother Heinrich, the family estates in Luxembourg, Brabant, Flanders, and Holland, and the principality of Orange. Though his father was a Protestant, he was brought up as a Catholic at the court of the Queen Regent, Maria of Hungary, at Brussels, and at the age of fifteen entered the service of Karl V. as page. The Emperor noticed his great promise, and gradually made him his most intimate confidant, placing him in 1555, at the age of twenty-two, in command of the Imperial army on the French frontier. Karl, on his abdication, recommended him warmly to Philip, in whose favour he remained for some time. It was he who concluded with France the peace of Cateau-Cambresis, for whose fulfilment he himself became one of the four hostages. He seems to have gained the favour of Henri II., who confided to him, while they were together on a hunting-party one day, his scheme for exterminating 'that accursed vermin' the Protestants. W. himself had as yet no decided leaning towards Protestantism, but the extreme ferocity of the plot struck him with abhorrence. He had, however, enough policy to conceal his aversion, and so gained his historic appellation of 'the Silent,' in no wise due to him on general grounds, since he was by nature gay and communicative. Returning to Brussels, he took his acknowledged place as leader among the *grands seigneurs* of the country. Wealthy by inheritance and by the dowry of his first wife, Anne of Egmont, he led a life of magnificent profusion far beyond even his great means. But troubles gathered fast round the country. The establishment of the new bishoprics (1560) and the tyranny of Cardinal Granvelle formed the signal for the commencement of the struggle. The united remonstrances of W., Egmont (q. v.), and Hoorn, ultimately supported by the Regent, Margaret of Parma, procured the withdrawal of Granvelle; but this concession was nullified by the establishment of the Inquisition, the true cause of the revolt. Finding a rupture imminent, W. determined at all hazards to maintain the cause of freedom and justice. He was not one of the original Gueux (q. v.), and he did not approve of all their proceedings, but Granvelle and Philip's other councillors had penetration enough to recognise in him an opponent more redoubtable than all the other leaders of the popular party put together. He recognised his danger, and when, in 1567, Alva (see ALBA) was appointed governor of the Netherlands, and placed in command of a crushing force of Spanish troops, W. withdrew to Germany, leaving Egmont and Hoorn to meet the fate which he had in vain tried to persuade them to avoid. He now replaced his former extravagance by the most rigid economy, but plunged deeper into debt so as to raise and equip armies for the rescue of his oppressed country. In 1568 his brother, the gallant Louis of Nassau, invaded Friesland, and he himself marched an army of 30,000 men into Brabant. Louis was routed by Alva at Jemmingen, but that wily commander refused to give battle to Orange, who was forced from lack of money to retreat and disband his army. In the next year he and his brothers brought their swords to the assistance of Coligny and the French Huguenots, but did not make another attempt upon the Low Countries until 1572. He had issued letters-of-marque to a number of privateers, called, in imitation of the Gueux, 'beggars of the sea,' and these in April 1572 captured the port and fortress of Brill. This was the first gleam of success which had fallen to the lot of the patriots, but it was soon to be overclouded. With an army of 24,000 men W. crossed the Rhine. Holland, Zeeland, Guelderland, Overyssel, and Utrecht appointed him stadtholder for Philip, to whom they had not yet renounced allegiance. The St. Bartholomew Massacre, however, crushed all hopes of aid from France, and the Spanish troops overran the whole of the North Netherlands, taking fortress after fortress. Haarlem was taken (July 1573) after a siege of seven months, and was devoted to fire and sword with the cruelty which characterised the Spanish soldiers above all others even in that cruel age. Alkmaar, however, held out, and the Dutch gained some naval victories. The 14th of April 1574 witnessed the most cruel blow of the whole war, alike to Orange personally and to the patriotic cause, in the defeat at Mooker-Heide, where Louis and Henry of Nassau, the prince's two brothers, who were marching northwards with aid from France, were both slain by the Spaniards under Avila. In the autumn, however, the cause revived. Leyden was relieved on the 3d of October by W. and the French admiral Boisot, who had driven the Spaniards away by breaking the dikes and flooding the surrounding country. It had borne famine and the other horrors of a siege with a heroic constancy which has rendered it for ever famous in history. Conciliation was tried fruitlessly at the conference of Breda (March 1575), and in the next year it seemed as if there were some possibility of the five Southern provinces which had remained faithful to Spain joining their Northern sisters. The *Pacification of Ghent*, however, was of

short duration; for, though it withstood the *Perpetual Edict* by which Don John of Austria, Alva's successor, attempted to conciliate the Walloon provinces, and though it even survived the disastrous defeat suffered by the patriots at Gembloux (31st January 1578), it could not resist the politic measures of Alessandro Farnese, who succeeded Don John, and the Southern provinces abandoned their last chance of freedom. Gradually the Spaniards lost their hold upon the North, and the division became more complete. The *Union of Utrecht*, which established the Dutch Republic, was signed on the 23d January 1579, and the United Provinces declared their independence on the 26th July 1581. W. remained practically at the head of affairs, though for some time the Archduke Mathias of Austria was the nominal ruler, and was succeeded by the Duke of Anjou, who had not even the nominal rule of Holland and Zeeland, where the Prince of Orange was supreme. Anjou was expelled in 1582, and his successor had not been chosen when the death of W. occurred. As early as 1580, Philip had offered a reward of 25,000 crowns and a patent of nobility for his assassination, which was more than once attempted. At last, on the 10th July 1584, he was shot in his own house by a man named Balthazar Gérard, half ruffian, half fanatic, whose only good quality seems to have been the almost superhuman courage which he evinced in enduring the inhuman tortures with which he was executed. So died one of the greatest of all patriots, a man fit to stand in the scale of character beside Washington and above Cromwell; while in ability, whether political or military, he fell in no way short of either. He had publicly professed the Calvinist faith in 1572, and showed the most earnest and sincere piety, but was no more bigoted as a Protestant than he had been as a Catholic. He was four times married, his second wife being Anne of Saxony, his third Charlotte of Bourbon, and his fourth Louise de Coligny, the daughter of the great French Huguenot. Two of his sons, Maurice and Frederic Henry, succeeded him in turn as stadtholder. See Motley's *Rise of the Dutch Republic* (Lond. and New York 1856), which may almost be called a biography of W. See also Gachard's *Correspondance de Guillaume le Taciturne* (Brussels 1847–56), Klose's *Wilhelm I., von Oranien* (Leip. 1864), Hermann's *Wilhelm von Oranien* (Stuttg. 1873), and Juste's *Guillaume le Taciturne d'après sa correspondance et les papiers d'état* (Bruss. 1875).

Will'iam and Mary College, at Williamsburg, in Virginia, the oldest college next to Harvard in the United States, received a charter in 1693 from William and Mary at the instance of Dr. James Blair, the commissary of the Bishop of London. Certain revenues were at the same time devoted to it, which were lost at the Revolution. It has a library of 4900 vols., and (1875) had 65 students and 7 professors.

Will'iams, Edward (Cymr. *Iolo Morganwg*), born at Llancarvan, Glamorganshire, in 1745; with Owen Jones and Pughe edited the *Myvyrian Archæology* (3 vols. 1801–7), and himself published, among other works, *The Fair Pilgrim, a Poem translated from the Welsh* (1792). To this he appended specimens of Druidical 'Triads,' which, after a long-protracted controversy and on the non-production of their MSS., are commonly looked on as a literary forgery. A friend of Southey, W. by trade was a stone-mason, and worked for some years in London, but died at Flemingstone, Glamorganshire, 17th December 1826, leaving a posthumous Welsh work, *Secrets of the Bards of the Isle of Britain* (1829). See E. Waring's *Recollections of E. W.* (1850).

Will'iams, John, the 'Martyr of Erromanga,' one of the greatest of modern Christian missionaries, was born at Tottenham High Cross, near London, January 29, 1796, and began life as an ironmonger's apprentice. In 1816 he sailed for the South Sea Islands, under the auspices of the London Missionary Society, and with the exception of about four years (1834–38), which he spent in England, the rest of his life was uninterruptedly devoted to the introduction of Christianity and civilisation among the Polynesians. At Rarotonga he constructed with his own hands a vessel of between 60 and 70 tons burden, with which he succeeded in visiting Tahiti on the one hand and the Navigators Islands on the other. No book of its kind ever attained so great a popularity as W.'s *Narrative of Missionary Enterprises in the South Sea Islands* (Lond. 1837), and it will long retain its value as a simple and manly record of a heroic life, and a trustworthy history of the most remarkable instance of savage communities being rapidly and radically transformed under the direction of a purely moral impulse. W. returned to the South Seas in 1838, and on November 20, 1839, he was massacred along with a fellow-missionary by the still barbarous natives of Erromanga. See John Campbell, *The Martyr of Erromanga* (Lond. 1842); and Ebenezer Prout, *Memoirs of the Rev. J. W.* (Lond. 1843).

Will'iams, Monier, son of a Surveyor-General of the Bombay Presidency, was born at Bombay, 12th November 1819, and after studying at King's College, London, and Balliol, Oxford (1838), gained an Indian writership and entered Haileybury College. In spite of a brilliant career there, circumstances forced him to resign his appointment, and returning to University College, Oxford, he was elected Boden scholar (1843), graduating B.A. in 1844. He occupied the Sanskrit chair at Haileybury (1844–58), was two years Oriental master at Cheltenham College, and in 1860 defeated Max Müller in a candidature for the Boden Sanskrit professorship at Oxford. His tenure of this office has been distinguished by his two visits to India (1875–76), there to collect subscriptions to found at Oxford an Indian Institute, a task that he has successfully achieved. Among his works are *A Sanskrit Grammar* (1846; 4th ed. 1877), an *English-Sanskrit Dictionary* (1851), *Rudiments of Hindustani* (1858), *Indian Epic Poetry* (1863), *A Sanskrit-English Dictionary* (1872), *Indian Wisdom* (1875), *Hinduism* (1877), and *Modern India and the Indians* (1878).

Will'iams, Roger, the founder of the state of Rhode Island, born in Wales about 1599; passed from Sutton's Hospital to Pembroke College, Cambridge, in 1623, and graduated in 1627. He obtained a benefice in Lincolnshire, but, embracing 'Separatist' views, left England in 1630 for America. There he became assistant to the Rev. Ralph Smith, of Plymouth, supporting himself meanwhile by manual labour, and bestowing much pains on the study of the Indian language. W. left Plymouth for Salem in 1633, and became pastor there in 1634, but the year after he withdrew from communion, and in January 1636 he was banished from the Massachusetts Plantation for his 'defamation both of the magistrates and churches.' About the 29th of May he founded the town of Providence as a 'shelter for persons distressed for conscience,' who should be 'ruled by the majority only in civil things,' and formed a 'covenant of peaceful neighbourhood' with the Indian tribes. In 1643 W. visited England, and through Sir Henry Vane secured a charter for his plantation, which was confirmed on his second visit to England in 1651. He remained in London till 1654, becoming acquainted with Cromwell and Milton, and in that year returned to Providence. From 1654 to 1657 W. acted ably as president of the colony, and in 1672 he refused to sanction the exclusion of Quakers from Rhode Island. He died at Providence in April 1783. A statue of W. has been erected by Rhode Island in the Capitol at Washington. See W.'s sixty-five *Letters* to the two Governors Winthrop (1863), his *Works*, edited by Reuben Aldridge Guild (6 vols., 1866–75), and the biographies by J. D. Knowles (1833), W. Gemmell (1846), and R. Elton (Lond. 1852), also M. Dexter's *As to R. W. and his Banishment from the Massachusetts Plantation* (Bost. 1876).

Will'iams, Rowland, D.D., born at Halkyn, Flintshire, 16th August 1817, from Eton (1828–36) passed to King's College, Cambridge, of which, having graduated in 1841, he became a fellow and tutor. Taking orders, he was appointed chaplain to the Bishop of Llandaff, vice-principal and Hebrew professor at Lampeter College (1850), select preacher to Cambridge University (1854), and vicar of Broadchalk, Wiltshire (1859). A foremost member of the Broad Church party, he was condemned by the Court of Arches (1862) for his paper on Bunsen's 'Biblical Researches' contributed to the famous *Essays and Reviews*, and having resigned his professorship prior to the reversal of that sentence by the Privy Council (1864), resided thenceforth at his vicarage down to his death there, 18th January 1870. Among his works were *Rational Godliness* (1855), *Christianity and Hinduism* (1856), *The Hebrew Prophets, a New Translation* (2 vols. 1868–71), and *Psalms and Litanies* (1872). See his *Life and Letters* (2 vols. Lond. 1874) by his widow, who has also edited *Stray Thoughts from the Note-Books of R. W.* (Lond. 1878).

Will'iams, Sir William Fenwick, Bart., K.C.B., a distinguished English general, was born at Halifax, Nova

Scotia, 4th December 1800, entered the Royal Artillery in 1825, and rose to the rank of first-lieutenant in 1827 and of captain in 1840. For service in Turkey he was brevetted major in 1843, and after taking part in the Turco-Persian Conference at Erzerum in 1847 was English commissioner for the settlement of the Persian boundary dispute in the year following. He received the Order of the Bath in 1852, and was nominated British Commissioner with the Turkish army in the East in 1854. Promoted brigadier-general, he heroically defended Kars with a Turkish garrison of 17,000 against Mouravieff with a greatly superior Russian force. The siege, which began on 16th June, lasted till 30th November 1855, when famine forced the general into surrender. On his return to England W. received, among other honours and rewards, a baronetcy with a life pension of £1000 a year, the rank of K.C.B., and the freedom of London City. He was returned to Parliament as a Liberal for Calne in 1856, and again in 1857, but retired in 1859, when he was appointed to the command at Woolwich. From 1860 he commanded the British troops in Canada, and in 1870 succeeded Sir R. Airey as Governor-General of Gibraltar. He resigned the post in 1875, and in 1877 retired from the army.

Will'iamsburg, the capital of James county, Virginia, U.S., on an elevated plateau between the James and York rivers. Though founded as early as 1632, W. contains little of interest except *William and Mary College* (q. v.). Its lunatic asylum, opened in 1773, is the oldest institution of the kind in the country. Pop. (1870) 1392. On May 5, 1862, W. was the scene of a fiercely contested battle in which the Federal troops ultimately came off victors.

Will'iams College, in Berkshire county, Massachusetts, U.S., was founded in 1793 in accordance with the will of Colonel Ephraim Williams, who fell near Lake George in 1755. It had (1875) 13 professors, 136 students, a library of 16,000 vols., and extensive and convenient college buildings. It has always shown a most praiseworthy zeal for science, the first observatory in the country having been erected here by Professor Hopkins. Its funds amount to $300,000.

Will'iamsport, a city of Pennsylvania, U.S., on the W. branch of the Susquehanna river, 202 miles N.W. of Philadelphia. It contains 32 churches, 3 public parks, &c., and has extensive foundries and boiler-works, but its importance is chiefly due to the lumber-trade of the Susquehanna, upwards of 900,000 logs being floated down to it annually from the upper reaches of the river. Pop. (1877) 16,030.

Will'iamstown, an important seaport of Victoria, on the S.W. shore of Hobson's Bay, 8 miles from Melbourne, with which it is connected by rail. Besides an extensive shipping trade, it has shipbuilding yards, patent slips, and a stone graving-dock capable of admitting vessels 500 feet long. The harbour is protected by heavy batteries. Pop. 8000.

Will'ibrord, St., 'Apostle of the Frisians,' born in Northumbria about 658, after a childhood passed at Ripon monastery, then ruled by St. Wilfrith, and twelve years of study in Ireland under St. Egbert, sailed in 690 for Friesland with twelve brother monks, to accomplish the work of conversion begun by Wilfrith (q. v.). Pippin of Herstal, who in 689 had wrested from Radbod, the Frisian king, a part of his territory, favoured the undertaking, and in his first visit to Rome (693) W. also received the sanction of Pope Sergius I., who three years later consecrated him Bishop of Utrecht under the name of Clemens. As such he laboured with high success among the Frankish subjects, with less among Radbod's, as also in Denmark and on Heligoland (699). The outbreak of war with Karl Martel (714) forced him to withdraw for a time to his monastery of Echternach, where, having meanwhile renewed his labours on Radbod's death (719), he died 7th November 739. See Thijm, *Der Heilige W.* (Münst. 1863), and a *Life of St. W.* (Lond., Burns & Oates, 1877).

Will'is, Nathaniel Parker, an American author, was born at Portland, in Maine, January 20, 1807. While still an undergraduate at Yale College, W. wrote a number of poems for his father's paper, *The Boston Recorder*, which were reprinted by S. G. Goodrich as *Sketches* (Bost. 1827), and from that date onwards his pen was never idle. Having spent six years (1831-37) in European travel, he settled down with his English wife, Mary Leighton Stace, on a beautiful estate, Glenmary, on the Susquehanna; but by 1844 he was back in England a sorrowing widower. On his return in 1846 to the United States, he married a daughter of the Hon. Joseph Grinnell of New Bedford, and established a new home at Idlewild on the Hudson, where he died, January 21, 1867. W., in spite of an almost lifelong struggle against consumption, kept up a remarkable activity in the lighter forms of literary production. He had been connected at one time or other with *The American Monthly Magazine*, *The New York Mirror*, *The Corsair*, *The New Mirror*, *The Evening Mirror*, and *The Home Journal*; he had contributed freely to English periodicals; and had published a large number of sketches, tales, and essays, such as *Inklings of Adventure* (1836), *Letters from Under a Bridge* (1840), *Hurry-graphs* (1851). He published a complete edition of his then extant works in 1846 in one volume.

Will'ow (*Salix*), a large genus of trees and shrubs belonging to the natural order *Salicinia*. The genus is predominant in the Arctic and N. temperate zones, becoming rarer in the tropics and southern hemisphere, and is not found in Australia or the Pacific Islands. It includes plants ranging from trees nearly 100 feet high to dwarf shrubs only rising an inch or two above the soil. From their long and interlacing roots, willows are invaluable to protect and fix the banks of rivers. Along roads, brooks, and in meadows they are often grown as pollards. The inner bark is tough and fibrous, and in N. America fishing-nets and lines are made of it. The bark of several species is bitter, containing a crystalline substance called *Salicine* (q. v.). Various species have already been noticed in articles OSIER and SALLOW, and of the large number which do not fall under these categories, a few only of the most utilitarian can be referred to here. The White W. (*S. alba*), spread through Europe eastward to the Himalaya, and often seen in marshy meadows in Britain, forms a large tree; its wood is light and elastic, available for carpenters' and wheelwrights' work, and its bark is serviceable for tanning. A series of hybrids between this and the Crack W. (*S. fragilis*), which bear the name of Bedford W. (*S. Russelliana*), are useful, quick-growing timber trees, and the bark contains more tannin than that of oak. *S. daphnoides* of Mid Europe and Northern Asia is remarkable for rapid growth. It is often chosen to fix the ground of railway embankments on sandy ridges or slopes. Its foliage furnishes cattle-fodder. The wood of *S. Humboldtiana*, a tree of about 50 feet in height, common in S. America, is much used for yokes and other implements. The Weeping W. (*S. Babylonica*) is widely distributed in Asia, and has elsewhere entered largely into cultivation as a shade-tree and for embellishments. *S. capensis* of S. Africa and *S. longifolia* of N. America also have long flexible withes. The sweet-scented male catkins of *S. Ægyptiaca* are used in the East in the preparation of kalaf, a liquid used as a stimulant and carminative; and in N. America a decoction of the roots of *S. nigra* is considered purgative and febrifugal.

Will'ow Moth (*Caradrina cubicularis*), a species of *Lepidopterous* insect, the larvæ of which feed upon grain, and chiefly upon wheat. It is of a dun or grey colour, the wings being apposed over the back in a state of rest. The hinder wings are pearly white. The larva is of a dull red colour often mixed with green, and the pupa or chrysalis is brown. The larvæ exist through the winter, and the pupa state is assumed in March or April.

Wil'mington, a city of Delaware, U.S., 28 miles S.W. of Philadelphia by rail, between the Brandywine and Christiania creeks, which join to form an affluent of the Delaware River, meeting it 1½ miles below W. The town has 50 churches and 5 daily and 8 weekly newspapers. In 1873 its manufactures were estimated at £21,000,000, consisting chiefly of machine work, $2,200,000; morocco and other leather, $2,050,000; foundry work and car wheels, $2,000,000; railroad cars, $2,000,000; carriages and wagons, $1,400,000; iron, $1,300,000; iron shipbuilding, $1,200,000; paper, $1,200,000; powder and chemicals, $1,200,000; flour and meal, $1,200,000; cotton goods, 1,100,000. Pop. (1876) 36,890.

Wil'mington, the largest town and chief seaport of North Carolina, U.S., on the E. bank of Cape Fear River, 30 miles from its influx into the Atlantic Ocean, 98 miles S.S.E. of Raleigh by rail. Vessels drawing not more than 16 feet of water can load here, but the harbour is now (1879) being considerably

deepened. W. has 22 churches, 12 schools, a theatre, and 5 newspapers (3 daily). Its exports in 1875 amounted to $10,000,000. They consist of lumber, shingles, cotton, and especially of naval stores, for which W. is said to be the leading market of the world. In 1877, of British vessels in direct trade with Britain, there entered the port 32 of 10,428 tons, with cargoes valued at £1035 (25 out of the 32 were in ballast); and cleared 43 of 13,575 tons with cargoes valued at £171,058; and in the carrying trade with other countries, there entered 30 of 8548 tons with cargoes valued at £2175, and cleared 19 of 5341 tons, with cargoes valued at £18,444. Pop. (1870) 13,416. W. was one of the chief ports visited by the blockade runners during the Civil War, and it was the last port open to the Confederates.

Wil'na. See VILNA.

Wil'son, Alexander, usually styled 'the American ornithologist,' was born at Paisley 6th July 1766. His youth was spent in weaving, peddling, and poetising. In 1790 he ventured to publish a volume of prose, and in 1792 his *Watty and Meg* had the honour of being ascribed to Burns; but in 1793 he was imprisoned for three days for lampooning one of the Paisley magistrates, and smarting under the disgrace he decided to leave the country. He landed at Newcastle in the United States July 14, 1794. From weaving and peddling he soon took to teaching, and acted as schoolmaster at various places; at Milestown, where he appears to have got into difficulty through a love affair, at Bloomfield, and at Kingsessing on the Schuylkill. An acquaintance formed at Kingsessing with William Bartram having stimulated his interest in American birds, he determined to collect and describe them, and for this purpose undertook a number of journeys in parts of the country that were then comparatively unexplored. The first volume of his great *Ornithology* was published in 1808 by Bradford of Philadelphia, and the second in 1810; other five appeared before his death, August 3, 1813; and an eighth and ninth were edited by George Ord in 1814. A continuation was executed by Lucien Bonaparte (Phila. 1825–33). W.'s *Poems* were published at Paisley in 1816 and at Belfast in 1844. *The Foresters*, a versified narrative of his journey to the Falls of Niagara, which first appeared in the *Portfolio*, has been frequently reprinted. See the Lives of W. prefixed to the Belfast edition of the *Poems* and to Sir William Jardine's edition of the *American Ornithology* (1832); Lucy Brightwell, *Difficulties Overcome* (Lond. 1860); Allan Park Paton, *W. the Ornithologist: a New Chapter in his Life* (Lond. 1863), and *The Verse and Miscellaneous Prose of A. W.*, edited, with memorial-introduction and notes by the Rev. A. B. Grosart (2 vols. Gardner, Paisley 1876).

Wil'son, Daniel, LL.D., a well-known archæologist, was born at Edinburgh in 1816, educated at the University of his native city, and after having been for some years secretary to the Royal Society of Antiquaries in Scotland, became in 1853 Professor of History and English Literature in the University of Toronto. He was president of the Canadian Institute (1859–60), and edited for four years the *Journal of the Canadian Institute*. His works are *Memorials of Edinburgh in the Olden Time* (2 vols. Edin. 1846–48; new ed. Edin. T. C. Jack, 1875); *Oliver Cromwell and the Protectorate* (ed. 1843); *The Archæology and Prehistoric Annals of Scotland* (ed. 1851; enlarged ed. 2 vols. 1863); *Prehistoric Man, Researches into the Origin of Civilisation in the Old and the New World* (2 vols. 1862; 3d ed. rewritten, 1876); *Chatterton, a Biographical Study* (1869); *Caliban, the Missing Link* (1873); and a volume of poems, *Spring Wild Flowers* (2d ed. 1875).—**George W.**, younger brother of the preceding, was born in Edinburgh, February 21, 1818. Educated at the High School and Surgeons' Hall of his native city, he was successively assistant to Professor Christison (1837) and Dr. Thomas Graham, Professor of Chemistry in University College, London (1838), extra academical lecturer on chemistry in Edinburgh (1840), a professor of technology in the University of Edinburgh, as also curator of the Industrial Museum (1855). He died November 22, 1859. W. was a man of exquisite beauty of character and grace of mind. He had the fancy of a poet and the luminous intellect of a savant. His chief works are *Life of Cavendish* (1851), *Life of Dr. John Reid* (1852), *The Five Gateways of Knowledge* (1856), and *Memoir of Edward Forbes* (1861) in conjunction with Archibald Geikie. See a Memoir by his sister, Jessie Aitken Wilson (Edinb. 1860).

Wil'son (Latinised *Volusenus*), **Florence**, a Scottish scholar and poet, was born near Elgin about 1500, and educated at King's College, Aberdeen. Proceeding to England he obtained the favour of Cardinal Wolsey, whose nephew he accompanied to Paris as tutor. On the death of Wolsey (1530) he found another patron in the learned Cardinal du Bellay, Archbishop of Paris, and was finally appointed by Cardinal Sadolet master of the public school of Carpentras. While here he wrote his famous dialogue, *De Animi Tranquilitate* (Leyden 1543), a monument of his classical erudition and the beauty of his Latin style. It contains several pieces of original Latin verse, which rival Buchanan's in elegance if not in strength. W. died at Vienne, in Dauphiny, about 1547.

Wil'son, Horace Hayman, a distinguished Sanskrit scholar, was born in London in 1786. He went to India in 1808 on the medical staff, but till his departure from Calcutta he was almost continuously employed in the Mint. Apart from his devotion to Sanskrit literature, he made himself intimately acquainted with the modern life of the Hindus, and took great interest in their social improvement. In 1833 he returned to England to be the first Boden Professor of Sanskrit at Oxford University, and shortly afterwards he was appointed librarian at the East India House, both which offices he held till his death, 8th May 1860. His published works, mostly on Sanskrit and kindred subjects, are very numerous. They were collected in 12 vols. (Lond. 1864–70), edited by Rost and Hall.

Wil'son, John, more familiarly known by his *nom de plume* of 'Christopher North,' was the son of a wealthy manufacturer, and was born at Paisley, May 18, 1785. Educated first in the parish manse of Mearns, next at Glasgow University for four years, he entered finally Magdalen College, Oxford, in 1803. There he gave good promise of his future career, and gained the Newdigate Prize in 1806; but his college achievements were chiefly athletic. In the following year he graduated, and soon after he bought Elleray, a beautiful little estate on the side of Windermere. In this district he had frequent intercourse with Coleridge, Southey, De Quincy, and above all, Wordsworth, the founder of the school of poetry to which W. in style belongs. To Coleridge's *Friend* he contributed a few essays. In 1810 he made a fortunate union with Miss Jane Penny, a beautiful, spirited, and accomplished woman, who had a powerful influence for good on her boisterous husband. Two years later appeared his *Isle of Palms*, a poem only read for half-a-dozen descriptive passages; and in 1816 he made a more serious essay with *The City of the Plague*. His private fortune was about this time curtailed by the misconduct of a relative. At Edinburgh, after passing advocate at the Scotch bar in 1815, he at once secured occupation and notice by starting *Blackwood's Magazine* (1817), a periodical intended to counteract the despotic Whiggery of Jeffrey's *Edinburgh Review*. W. was never nominally the editor, but was for long the principal contributor, sometimes writing nearly the entire monthly number. It is not wonderful that with support from such bright spirits as Lockhart, Hogg, and Maginn, he should have established a wide sway in literature. 'Kit North' was soon as well known as Jeffrey. In society and in his magazine, however, the rollicking litterateur many a time offended the minor laws of society. In 1820 he succeeded Dr. Thomas Brown in the chair of Moral Philosophy. The contest was singularly acrimonious, and it was W.'s misfortune to be opposed by an incomparably more exact thinker than himself, Sir William Hamilton. Politics decided the day. The Tory defeated the Whig. But it may at least be said for W. that he carried his genius into the professor's chair; and if he did not evolve a new ethical theory, he irradiated his subject with a stronger and richer eloquence than it had ever before received in a Scottish University. Seventeen happy and busy years went by, during which were written three tales, *Lights and Shadows of Scottish Life* (1822), *Trials of Margaret Lindsay* (1823), and *The Foresters* (1824), all abounding in the happiest descriptions of Scottish scenery. In 1837 the death of his wife almost broke his spirit. For a time he felt unfit for his accustomed labours; but he published in 1841 an *Essay on Burns*, and in 1842 *The Recreations of Christopher North*, a series of collected essays in three volumes. In 1851 he received a Crown pension of £300, and in the following year broken health compelled him to resign his chair. For two years he was laid aside, and he died in the city in whose streets he was known so well, April 3, 1854. In the collected writings of

Christopher North, edited by his son-in-law, Ferrier (12 vols. 1855-58), there is much that has lost the bloom so charming in the magazine pages, yet in them we have a literary influence that was second only to Scott's. He was by turns fierce and tender, poetical and coarse, broad in his literary sympathies, and vindictive in his political partisanship, but his work was always strong, full of imagination, and—a necessity for his magazine—delightfully readable. Now-a-days his poems and prose tales receive little attention, and his reputation rests on the classic *Noctes Ambrosianæ*, in which the early readers of *Blackwood* revelled with Christopher and his cronies as they mingled the poetry of laughter with the fierce gibings of party spirit over the steaming hippocrene. A condensed edition—*The Comedy of the Noctes Ambrosianæ*—was edited by Dr. Skelton in 1877. See *Christopher North: A Memoir of John W.*, by his daughter, Mrs. Gordon (1863; new ed. Thomas C. Jack, Edin. 1879).

Wil'son, Rev. John, D.D., F.R.S., missionary, philanthropist, and scholar in Western India, was born in 1804 at Lauder, Berwickshire, and educated at the University of Edinburgh. In 1828 he was sent out to Bombay by the Scottish Missionary Society, and in 1835 transferred his services to the General Assembly's India Mission. In 1843 he and his twelve colleagues in India joined the Free Church of Scotland. For forty-seven years W. was identified with progress of all kinds, spiritual, social, intellectual, and even administrative in Western India, more than any other man. As a missionary he founded two Christian colleges, established the first girls' schools, opened numerous boys' schools, and in vernacular as well as in English education was the pioneer; and the example was followed by the Government, which made him Vice-Chancellor of the University of Bombay. He made detailed tours all over Western and Central India from 1829 to 1839, which resulted in the establishment of vigorous missions, not only by his own Church, but by the Irish Presbyterians in Goojerat, and the United Presbyterians of Scotland in Rajputana. By pen, and voice, and personal influence, he caused or aided in the abolition of the slave-trade in Eastern waters and E. Africa; the stoppage of suttee and other iniquities encouraged by Brahmanism, the growth of toleration, and the protection by the legislature of the civil and religious rights of the natives. He founded a large native church and body of educated catechumens. As the friend of the successive Governors of Bombay and Governors-General of India, he was consulted on many political questions, from Lord Ellenborough's Proclamation of the Gates of Somnath, by Lord Elphinstone all through the Mutiny, by Sir Bartle Frere, and down to Lord Northbrook's trial of the ex-Gaikwar of Baroda. He was of essential service to his friend Dr. Livingstone in the last expedition of the heroic explorer of Central Africa, and it was W.'s students Chuma and Wykatane who brought home the remains. He aided Lord Napier in the Abyssinian expedition, two of his catechists, Gabru and Maricha Warka, having become the trusted counsellors of Prince Kassai of Tigré, the present *Negoos* or King Johannes of Abyssinia. As a man he was beloved by the natives, as well as Europeans, of all creeds and classes through four generations, so that he was affectionately known as W. *Kaka*, or 'Uncle W.' His life and influence purified English society in Bombay, and gave it a high ideal. As a scholar his most notable merit is that he was the first Englishman to expound the Zand literature of the Parsees from the original texts, and to decipher the Pali edicts of the first Buddhist Emperor Asoka, as graven on the rocks of Girnar, in the peninsula of Kathiawar, near Joonagurh. Like Mezzofanti, he had a marvellous genius for languages—Zand, Sanskrit, and their derived dialects; Arabic and Hebrew; Marathi, Goojarati, Hindi, Hindostani, and Persian. His familiarity with the most obscure characters and books of the Hindu sects enabled him in the Maharaj libel case to expose the adulterous practices of the Krishna priests (Vallabhacharyas), and to earn the gratitude not only of the High Court judges, but of the varied native communities of Bombay. His greatest book is *The Parsi Religion* (1842). He wrote *The Lands of the Bible*, still an authority on the Eastern Churches, which he had studied more profoundly and practically than any other English scholar at the time; *India Three Thousand Years Ago*, his most popular work; *Memoirs on the Cave-Temples of India*, *The Religious Excavations of Western India*, numerous missionary works in English and the vernacular languages of India, and a posthumous fragment forming one thick volume, *Caste*, on which he was occupied for many years. Dr. W. was summoned home to be Moderator of the Free Church General Assembly in 1870. On his death in Bombay in 1875, during the visit of H.R.H. the Prince of Wales, who desired to call on the venerable missionary, the whole city, from the governor to the humblest African whose liberty he had secured, followed the missionary to the grave. The citizens and the sacred town of Nasik had previously presented him with eulogistic addresses. The Asiatic Society of Bombay twice honoured him thus. His first wife, Margaret W., and his second wife, Isabella W. were, as pioneers of female education, as remarkable and beloved as W. See Dr. George Smith's *Life of John W., D.D., F.R.S., for Fifty Years Philanthropist and Scholar in the East* (Lond., Murray, 1878).—**Andrew W.**, son of the preceding, was born at Bombay in 1830, and studied at Edinburgh and Tübingen. He first attracted notice by a contribution to the *Edinburgh Essays* (1857) entitled *Infante Perduti*. W. subsequently edited the *China Mail* for three years, visited Japan when it was thrown open to Europeans, lived for a time in Southern China after the Chinese fashion, wrote *The Ever-Victorious Army*, a history of the campaign in which Colonel C. G. Gordon, now the Khedive's Governor in Equatorial Africa, suppressed the Tai-ping rebellion, was in America in the early years of the Civil War, and returning to the East edited the *Bombay Gazette*, and made a long journey through the upper valleys of the Himalaya, of which he has given a graphic and brilliant description in his *Abode of Snow* (1875). He has been a frequent contributor to *Blackwood* and other magazines. W.'s latest work (1879) is *Schiller* in the series of 'Foreign Classics for English Readers.'

Wilson, Sir Archdale, G.C.B., the Indian officer who commanded at the great siege of Delhi, was born at Didlington, Norfolk, in 1803. At sixteen he entered the Bengal Artillery, to the lustre of which he added at the siege of Bhurtpore, the affair of Lahore, and the capture of Delhi. After the successive deaths of Generals Anson and Barnard, General Reed succeeded to the command at Delhi in 1857. Finding his health unequal to the strain, that officer made W. brigadier-general, and resigned the command to his hands. That was at the time when the little British force on the Ridge was the besieged rather than the besiegers. What it wanted was a siege train of far-reaching guns. As an artilleryman W. saw this. Though never hopeful, though naturally weighed down by a sense of his responsibility, W. had the merit to trust the two men who finally took Delhi—Colonel Baird Smith (De Quincey's son-in-law) and Captain Alec Taylor. Hence the substantial justice of Lord Canning's order when Delhi fell, 'In the name of outraged humanity, in memory of innocent blood ruthlessly shed, and in acknowledgment of the first signal vengeance inflicted upon the foulest treason, the Governor-General in Council records his gratitude to Major-General W. and the brave army of Delhi. He does so in the sure conviction that a like tribute awaits them, not in England only, but wherever, within the limits of civilisation, the news of the well-earned triumph shall reach.' Made a baronet by patent, Sir Archdale W. was succeeded by his nephew, the present Sir Roland Knyvet of Delhi, on 9th May 1874. Sir John Kaye fairly states the facts of W.'s Delhi command in the 2d and 3d volumes of the *History of the Sepoy War*, but a better book is the *History of the Siege of Delhi, by an Officer who served there* (Dr. Ireland, it is said), and published by Adam and Charles Black (Edin. 1861).

Wil'son, Sir Robert Thomas, an English general, was born in London in 1777. He received the rudiments of a classical education at Westminster and Winchester, and at an early age (1794) obtained a commission in the 15th Light Dragoons, at that time serving in the Netherlands. Though the British forces returned home in 1796 he had already seen a good deal of hard service, and not long after he took part in the suppression of the Irish rebellion (1798), and was present in all the engagements of the campaign of the Helder (1800). We next find him with the Austrian army in Italy, with Sir Ralph Abercromby in Egypt (1801), and with Sir David Baird at the Cape of Good Hope (1805). As a member of Lord Hutchinson's staff he was a witness of the battles of Eylau and Friedland, and he was employed to convey despatches from St. Petersburg to England and from England back to St. Petersburg. In the Peninsular War he had command of the army of Portugal (1808-9), and rен-

dered effective service; but his next employment was again rather diplomatic than military, Lord Castlereagh sending him to Constantinople as attaché to Mr. Liston's mission. During the final struggle between Russia and the French he was present at the headquarters of the Russian army, took part in the battles of Lützen, Bautzen, Dresden, and Leipzig, his services being acknowledged by the presentation of the Order of St. George from the hand of the Emperor himself. In 1814 he served for a time in Italy, and in 1815 he assisted in the escape of Lavalette at Paris and was condemned to three months' imprisonment. The free expression of his opinions against the government action in regard to Queen Caroline caused him to be dismissed from the army (September 1821), but he was afterwards restored, attained the rank of general in 1841, and was governor of Gibraltar from 1842 to 1849. For a number of years (1818–31) he was Member of Parliament for Southwark in the Liberal interest. He died in London, 9th May 1849. W. wrote *History of British Expedition to Egypt* (Lond. 1802); *Inquiry into the Military Force of Britain* (1804); *Remarks on the Russian Army and Sketch of the Campaigns in Poland in* 1806 *and* 1807 (1810); *Narrative of Events during the Invasion of Russia by Napoleon* (1860), and *Private Diary of Travels, &c., in the Campaigns of* 1812–14 (2 vols. 1861)—the two last being edited by his nephew and son-in-law, Rev. Herbert Randolph. These works are in the main valuable contributions to the history of the times, and consist for the most part of the writer's personal experiences, narrated with no small liveliness and vigour. See *Life of Sir R. W. from Autobiographical Memoirs* (2 vols. Lond. 1862) also edited by Randolph.

Wil'ton, a market-town of Wiltshire, England, stands at the confluence of the Wiley and Nadder, 2½ miles W.N.W. of Salisbury by rail. Its church (1842) is a richly-decorated Lombardic structure, with a campanile 120 feet high; and near the town is the mansion of the Earls of Pembroke, with fine art collections, and a library where Sydney wrote his *Arcadia*. W. returns one member to Parliament, and has a celebrated carpet factory, employing 500 hands. Pop. (1871) 8865. The seat of a bishopric (909–1050), and the scene of Ælfred's defeat of the Danes (871), W. has dwindled as Old Sarum rose into importance.

Wilt'shire, or **Wilts**, an inland county in the S.W. of England, bounded N. and N.W. by Gloucestershire, N.E. by Berkshire, S.E. by Hampshire, W. by Somersetshire, and S.W. by Dorsetshire. Area, 859,303 acres; pop. (1871) 257,177. The county is almost quadrangular in form, measuring from N. to S. 54 miles, and from E. to W. 37 miles. It is divided into two divisions by the Vale of Pewsey extending E. and W., the northern, a fertile tract rising near the N. boundary in the direction of the Cotswold Hills, and the southern, a varied district broken by downs, some of considerable height, and intersected by fertile and well-watered valleys, especially along the rivers Avon, Willey, and Nadder. Marlborough Downs belong to the northern district; the great Salisbury Plain to the southern. The chief geological strata are cretaceous, forming part of the great central chalk district of England. Ironstone is found abundantly; the yield in 1878 was 79,176 tons. The principal eminences are Inkpen Beacon (1011 feet), the highest point in the chalk formation in England; Alfred's Beacon (800 feet), and Westbury Down (775 feet). The northern chalk district and the northern part of the county belong to the basin of the Thames, the southern chalk district and the Vale of Pewsey to the basin of the Salisbury Avon, and the western side of the county to the basin of the Severn. The plains in the N. and N.E. sloping to the Thames are of extraordinary fertility, and are covered with large dairy-farms. In the S. and S.E. are ranges of downs, thinly populated, but producing abundant pasture for sheep. The gross rental of W. for 1878 was £1,747,430. In the same year there were within W., under corn crops, 218,471 acres; green crops, 101,035 acres; grasses under rotation, 84,102 acres; permanent pasture, 328,736 acres; and the farm-stock was 22,566 horses, 87,395 cattle, 685,980 sheep, and 70,016 pigs. W. contains interesting antiquities, many from the ante-Roman period. Within it are Avebury (q. v.) and Stonehenge (q. v.). See Sir R. C. Hoare's *Ancient Wiltshire*.

Wimm'era, a district of the colony of Victoria, occupying its N.W. portion, and having an area of 25,000 sq. miles. It consists for the most part of wide sandy plains, thinly grassed and badly watered, yet supporting great flocks of sheep, for which water is obtained by digging wells from 80 to 140 feet deep. The plains are intersected by belts of scrub and forest, and there are also patches of land suited for agriculture.

Wincan'ton, a market-town of Somersetshire, England, on the Cale, 18 miles E.S.E. of Glastonbury by rail, has a town-hall (1878) in Queen Anne style, and carries on a trade in corn and cheese. Pop. (1871) 2377.

Win'cey is a mixed textile fabric, consisting of a cotton warp with a worsted weft. Winceys are woven either plain or twilled, and though generally made of grey, drab, or brown colours without any pattern, in fancy winceys checks and stripes are introduced, but the colouring is always sober. The W. manufacture till recently was extensively and successfully prosecuted at Aberdeen and Perth in Scotland, but for the present the current of fashion is adverse to this strong and economical fabric. It is chiefly used for gowns and petticoats, and of late years it has been commonly employed for men's shirts, &c.

Win'chester, a city of Hampshire, England, 66½ miles S.W. of London by rail, stands at the foot and on the slope of a hill that rises westward from the right bank of the Itchen. The ancient High Street, with narrow thoroughfares branching off at right angles, ascends for about three-quarters of a mile towards the Castle Hill, round or on which, and in the level valley by the water-side, most of the older buildings of W. are situated. A blending of five centuries of styles, the Cathedral outwardly presents a plain and sombre aspect, the central tower (138½ feet high) seeming too low for a building 558 feet long by 208 across the Norman transepts. But the interior is unsurpassed—the long-drawn nave (1394–1410), its bossy roof upborne by massive piers; the choir and sanctuary (1320–50), over whose lace-like reredos the eastern window glows with its pristine hues; and the graceful presbytery (*c.* 1202) contrasting with an ornate Lady Chapel (1470–1524). Of Birinus's church (648), and the cathedral dedicated to St. Swithin (q. v.) by Bishop Æthelwold (980), few traces remain except the relics of kings and saints gathered by Fox into six gilded coffers; but to Walkelin's structure (1079–93) belongs Rufus's tomb, removed to the Lady Chapel (1868); and later monuments are the stately chantries of Langton, Wykeham (q. v.), Beaufort, Waynflete, Fox, and Gardiner, the tombs of Izaak Walton and Jane Austen, the Sumner cenotaph, and Wilberforce memorial screen (1875). St. Mary's College, oldest of English Public Schools (q. v.), was founded by William of Wykeham (1387) as a nursery to his Oxford New College. It still retains the founder's general plan—two main quadrangles, gateway and chapel towers (the latter rebuilt 1863), an exquisite chapel, hall, and cloisters 132 feet square, additions being the schoolroom (1687), 'Commoners' (1841), converted (1869) into class and lecture rooms. Under late statutes the present foundation consists of a warden, ten fellows (temporarily sixteen), a headmaster, and 70 scholars; and in June 1879 there were 24 masters and 385 boys, while among former Wykehamists occur the names of Warham, Sir Thomas Browne, Ken, Otway, Young, Collins, Joseph Warton, Bowles, Sidney Smith, Lowe, and Cardwell. The latest History of the College, with its *argot*, its *Dulce Domum*, its two rebellions (1793 and 1818), &c., is Adams' *Wykehamica* (Oxf. 1878). Neither the twelve ancient (survivors of sixty-five) nor the three modern churches can vie in beauty with the Hospital of St. Cross, lying 1 mile to the S. across the water-meadows. Endowed by Bishop de Blois (1132) and augmented by Cardinal Beaufort's Almshouse of Noble Poverty (1444), this ancient charity consists of a master and thirteen black-robed brethren, and still dispenses the 'Wayfarer's Dole' of beer and bread. One side of its quadrangle is occupied by a noble cruciform church (1171–1292; restored 1865), a specimen of pure Transition-Norman but for the splendid Decorated western window. Other striking objects are the ivy-clad ruins of Wolvesey Castle (built in 1138, and demolished by Cromwell in 1645); the deanery; the W. and King's Gates (the latter surmounted by the 13th c. church of St. Swithin); the 15th c. Butter Cross, 43 feet high (restored 1865); the handsome Guild-hall (1873), designed by Sir Gilbert Scott in Geometrical Gothic and containing a museum; the School of Art (1876); a diocesan training college (1863); the new Assize Courts (1874); Wren's unfinished royal palace (1683), now used for infantry barracks; and, on the Castle Hill, the church-like hall of Henry III.'s

palace (restored 1874–76), where Raleigh was tried, and in which the 16th c. 'Round Table' hangs. No important manufactures have replaced the once famous woollen trade of W., which publishes two weekly newspapers, and returns two members to Parliament. Pop. (1871) 14,785. The Celtic *Caer Gwent* ('champaign fortress'), Roman *Venta Belgarum*, and Old English *Wintanceaster*, W. was conquered by Cerdic in 519, and for 300 years continued the capital of Wessex, being raised to a bishopric by Cenwealh (*c.* 639). In 1013 it submitted to Swegen, in 1042 was the coronation place of Eadward the Confessor, as afterwards of many English kings. Under Henry I. it boasted a cathedral, two royal minsters, sixty churches, a palace, two castles, and a mint; but from the civil wars of Stephen's reign its prosperity declined, the blow of a seven days' siege by Cromwell (1645) being succeeded by the terrible pestilence of 1666. Prior to this it had been the scene of the marriage of Henry IV. to Joan of Navarre (1404), and of Mary I. to Philip of Spain (1554). See Milner's *History of W.* (2d ed. 1809), and Mackenzie Walcott's *Memorials of W.* (Lond. 1866).

Win'chester, a town of Virginia, U. S., 71 miles W. of Washington. It has 15 churches, 2 weekly newspapers, 5 tanneries, iron foundries, alkali-works, and a glove manufactory. Pop. (1870) 4477. W. is the key to the Shenandoah Valley, and its possession was frequently contested during the Civil War.

Win'cing Machine', in dyeing and calico-printing, is a reel or winch placed over the vertical partition of a vat, so that cloth may be drawn from one compartment and discharged into the other according as the handle is turned.

Winck'elmann, Johann Joachim, the famous archæologist and writer on the history of art, was born at Stendal, 9th December 1717, studied at Berlin, Halle, and Jena, and was appointed (1748) secretary to Count von Bünau, the Saxon minister, who dwelt at Nöthenwitz, near Dresden. His position gave him access to the art treasures of that capital, and here he first found opportunity of gratifying his nobler tastes and sentiments. Archinto, the Papal nuncio at Dresden, became acquainted with W. and offered to procure him an office in Rome. There was one condition annexed—W. must become a Catholic. His journey there was, however, deferred for a year. In the interval he published *Gedanken über die Nachahmungen der Griechischen Werke in der Malerei und Bildbauerkunst* (1754, translation, Glasgow 1766), and two other works on the same subject. In 1755, having received a royal pension, he proceeded to Italy, where he was received with favour. Rome answered all his expectations—like Thorwaldsen, he used to date his life from the day he entered it. How he studied the works of art around him we know from the works he has written—works that 'opened the eyes of the Italians themselves.' Of these the chief were *Anmerkungen über die Baukunst der Alten* (Leips. 1762), *Monumenti Antichi Inediti* (2 vols. Rome 1767, German translation 1791–92), and *Geschichte der Kunst des Alterthums* (Dresden 1764, new edition, Berl. 1870; translation by Lodge, Lond. 1850). This, his greatest work, was completed by the publication of *Anmerkungen über die Geschichte der Kunst* (Dresden 1764). W. met his death in a manner that might form a fit subject for the most pathetic of tragedies. After long years of absence he desired to revisit his native land. He began his northward journey, but he found it was 'to drag at each remove a lengthening chain.' He was no sooner beyond Italy than he passionately desired to return. At Vienna he was received with kindness and presents, but he proceeded no further. As he was hurrying back to Rome some signs of wealth attracted the attention of a miscreant named Francesco Arcangeli, by whom he was murdered in an inn at Trieste on the morning of 8th June 1768. W.'s great service to his own and to all future time is that he taught men to look at the art-works of the ancients in a direct, simple, purely objective and therefore true manner. This he did by pointing out wherein the excellence of classic art consists—viz., its 'ideality' and 'placid grandeur.' It strives to represent as far as possible a perfect conception of beauty, marred by no peculiarities or side developments. See Goethe's *W. und sein Jahrhundert* (1805), the complete edition of W.'s works by Fernow, Meyer, and Schulze (Dresden 1808–25; new ed. 1838), and the very full Biography by Justi (2 vols. Leip. 1866–72; Eng. trans. Lond. 1879).

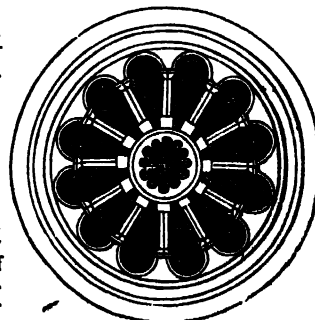
Win'dage is the difference between the bore of a gun and the diameter of the projectile, varying from ·15 to ·9 of an inch for spherical projectiles. For rifled guns the W. is much smaller.

Win'dage (from cannon-balls), or **Wind Contusions**. It sometimes happens, in the practice of military surgeons, that cases of severe internal injury occur in warfare in which there are no external appearances of severe wounds or injury. Thus, there may be rupture of the liver, concussion of the brain, or even comminuted fracture of a bone, the neighbouring tissues bearing no marks in proportion to the severity of the internal lesions; so that it was long conjectured that solid objects projected through the air with great velocity might produce such injuries, indirectly, by aërial percussion, the hurt being inflicted either directly by the force with which the air was driven against the part, or, indirectly, by the rush of air to refill the vacuum created by the rapid passage of the ball. This hypothesis, however, is now generally rejected, the true explanation being that the body is really struck by the projectile in an oblique direction, the comparative escape of the soft tissues being accounted for by the peculiar direction, the degree of obliquity with which the missile impinges on the elastic skin, together with the situation of the structures injured beneath the surface, relatively to the weight and momentum of the ball on one side, and hard resisting substances on the other. See article 'Gun-shot Wounds' in Holmes' *System of Surgery*.

Win'dau, a seaport of Russia, province of Kurland, at the mouth of the river W. in the Baltic, on a deep harbour inaccessible to large ships through a sandbar. W. has a Lutheran church, a Russian church, a Catholic chapel, and a synagogue. Its exports in 1877, chiefly timber, linseed, corn, tar, and pitch, amounted to £178,199, its imports to £12,145. In the same year 387 vessels entered the harbour. Pop. (1875) 4108.

Win'dermere, the largest of the English lakes, being 10 miles long by 1 mile broad, belongs to Westmoreland, though mostly enclosed by Lancashire. With clustering islets, richly-wooded or 'holly-sprinkled' slopes, and bold or gentle headlands breaking the banks into countless bays, W. has more the character of a broad and placid river than of a mountain-locked lake like Wastwater or Ullswater. Only to the N. the Langdale Pikes, Bowfell, and Scawfell form a majestic background. Steamers ply constantly between Ambleside at the northern head, Bowness, and Newby Bridge at the foot of the lake, whose yachts are among the fastest sailers built. With a depth of 240 feet, W. is but rarely frozen over, but in the winter of 1878–79 skating went on over its entire surface.

Wind'ham, William, an English statesman, was born in London, 3d May 1750, of an old Norfolk family, his father being the owner of Felbrigg Hall in that county. He was educated at Eton, at Glasgow University, and at University College, Oxford, which he entered in 1761. After travelling on the Continent, and starting for the North Pole in 1773, he was so seasick that he had to be put ashore again in Norway. Returning to England, he first attracted attention by a speech at Norwich, early in 1778, in opposition to the American War and the ministerial policy in general. At the general election of 1780 he contested Norwich unsuccessfully, but was returned at the general election of 1784. He had meanwhile lived principally in London, become intimate with Burke, Fox, and Johnson, who had the greatest admiration and respect for him, and had also visited Ireland as secretary to the lord-lieutenant, Lord Northington, a post which he resigned after a few months, perhaps on account of conscientious scruples. In Parliament he acted with the Opposition up to the outbreak of the French Revolution, making himself known by his 'insinuating' oratory, as Canning described it, and distinguishing himself as one of the managers of the impeachment of Warren Hastings in 1787. On the outbreak of the Revolution, he followed Burke in deserting the Whig cause and going over to the Government. He of course strenuously supported the war, and in 1794 became Secretary at War in Pitt's cabinet, with which he went out of office in 1801. Under the Grenville administration (1806) he again held office as Colonial Secretary, and brought in and carried, in spite of vehement opposition, a bill for army reform. Its effect was to limit the term for military service, making the infantry enlistment valid for seven years, the cavalry and artillery for ten years; the former renewable of a second term of seven years,



the latter for second and third terms of six and five years respectively. There were also numerous provisions for increased pay and pensions both to officers and men. W. declined the offer of a peerage, and went out of office in 1807. He afterwards strongly opposed the Copenhagen and Walcheren expeditions, but did not again take any very prominent part in politics. He died in London, 3d June 1810. His contemporaries unanimously describe him as the model, both physically and mentally, of an English gentleman—able and high-minded, though so much given to paradox as to earn for himself the nickname of 'the Weathercock.' His conversation was brilliant, his literary acquirements wide, and his power as a debater very great. See his *Speeches*, edited, with a Life, by his secretary, Mr. Amyot (Lond. 1812), and his *Diary from* 1784 *to* 1810, edited by Mrs. Baring (Lond. 1866).

Wind Instruments, musical instruments the sounds of which are produced by the action of the breath of a player or of a pair of bellows on a column of air. The organ is really a collection of W. I. of different kinds, forming a species of orchestra. Ordinary W. I. are constructed of wood, such as the flute, piccolo, clarionet, basset horn, oboe, and bassoon; or of metal, such as the horn, trumpet, serpent, cornet-a-piston, ophicleide, saxhorn, and bombardon. Those of wood have a soft tone, those of brass a loud and powerful tone. W. I. were used sparingly in the early days of the orchestra, but with great liberality in Handel's time, when for every three stringed instruments two W. I. were used. The proportion at present is greatly less. By additional finger keys, &c., W. I. have been greatly improved in the last half-century. Sax of Brussels is one of the best makers. The bagpipe is a wind instrument of a very primitive type, with a leather case as a wind-chest attached to three pipes.

Wind'lass, a mechanical contrivance used on board ship for raising anchors and other heavy masses. The principle of its action is the same as that of the capstan, from which it differs mainly in the horizontality of its axis. It consists essentially of a large roller, supported in *checks* or *W.-bitts*, and rotated by handspikes fitting into mortices in the W., or by means of a single handle with or without additional wheelwork. To prevent the W. from slipping back under the severe pull of the chain, a strong ratchet-wheel is fixed on the roller, and into its teeth a number of *pawls* pivoted in an upright post called the *pawl-bitt* fall as the W. rotates, so as to sustain the stress as the spikes are being shifted for a new purchase.

Wind'mill, a mill of any kind the motive power of which is derived from the impulse of the wind upon a series of revolving sails. Beckmann (*History of Inventions*) is of opinion that windmills were invented in Europe, and not in the East as some authors affirm; and he rejects as unfounded a statement made by Pomponius Sabinus, who flourished in the 15th c., that the Romans used such machines. Germany was probably the country, and the 11th c. the period of their origin. It is certain that windmills were erected in Europe during the First Crusade. In the 12th c. they had become so common that Pope Celestine III. decreed that watermills and windmills were tithable. There are two kinds of windmills—*vertical* and *horizontal*. The vertical, which is the form chiefly in use, consists of a lofty tower, having at the summit a *wind-shaft* or *axle* mounted in bearings. The outer end of the axle is raised about 18° from the horizon, and has attached perpendicularly to it four or five radial arms, about 30 or 40 feet long. Each arm carries a kind of lattice-work, which is covered with canvas to receive the action of the wind. The *sails* thus formed are set at an angle to the axle, so that the wind blowing directly in the face of the mill causes them to revolve in a direction transversely to its own plane of motion. The movement thereby acquired by the axle is transferred by bevel wheels to a vertical *main shaft*, which gears with machinery for performing the specific work of the mill. With a moderate wind the extremities of the sails are estimated to travel at the rate of from 20 to 30 miles an hour. Various reefing arrangements for adjusting the extent of canvas to the force of the wind are adopted. An ingenious automatic device for attaining a pretty steady velocity with wind of varying pressure has been introduced recently, and consists in forming the sails of a framework filled with louvre-boards, which open or close according as the wind blows strongly or lightly. As the direction of the wind is very variable, some means become necessary for bringing the mill to face the wind. The old German method of accomplishing this was to pivot the whole structure on a central post. The Dutch method, which is in very general use, consists in making the W. cap only movable by resting it on rollers, so that it can be turned by a long hand-lever. Sir William Cubitt invented a novel and effective plan of causing the wind itself to adjust the W. cap to its proper position. A set of small sails acting as a vane are mounted opposite the large sails, on an axle transverse to the wind-shaft. So long as the W. faces the wind, the vane remains motionless, but a change in the direction of the wind immediately moves the vane, and its axle actuates gearing which turns the W. cap. A horizontal W. is so named because its sails revolve in a horizontal plane. It is very seldom employed, as its effective power is only one-third or one-fourth that of a vertical W. The principal uses of windmills are in grinding corn, in driving sugar-mills and wood-sawing machinery, in raising water from wells, and in draining land either by working pumps or turning a water-wheel. Steam-power is, on account of its steadiness and certainty of action, to a great extent superseding the W., but in countries where level stretches of land occur, and water is not available, it is still extensively used. In the United States, Corcoran's patent W., which adjusts itself to all variations of the wind either of direction or force, is an important article of manufacture. It is largely exported to the W. Indies, S. America, and New Zealand.

Win'dow, an aperture in the wall of a building for the admission of light and air. Modern domestic windows are usually rectangular openings occupied by movable frames filled with glass. The glazed portion or *sash* is hung or hinged in a *frame*, the horizontal stone forming the top of the window is the *lintel*, that at the bottom the *sill*, the sides of the opening are the *jambs*, and the portion between the outer face of the wall and the frame is the *reveal*. Architraves and other mouldings commonly appear on the exterior. *Venetian windows* are large openings divided by piers or columns into three lights, sometimes arched. Windows projecting in a polygonal or semicircular form from the wall are termed *bay* or *oriel* windows: they were first introduced in the Perpendicular style. The architecture of the Egyptians and Greeks was practically windowless, light and air having been admitted by openings in the roofs. Small openings in the walls of Roman houses were not uncommon. They were at first closed by shutters or covered with a kind of lattice or trellis work; and afterwards a transparent stone, called *lapis specularis*, the modern mica, brought from Spain and Cappadocia, was employed. Excavations at Pompeii have shown that glass windows were also used in the early days of the empire. The traceried W. peculiar to Gothic architecture was developed from the most simple forms. In Old English and Early Norman buildings the windows are small and arched; the interior, and sometimes the exterior, being widely splayed. Some Norman windows have two lights set in a shallow recess and surmounted by a single arched dripstone, and mouldings are frequently introduced. Early English windows are for the most part long and narrow, with acutely-pointed heads. They occur singly, or in groups of two, three, five, or seven lights under an acute arch. Piercing the tympanum space above the lights with a trefoil, or other geometrical figure, was the first step towards the development of the elegant and elaborate Tracery (q. v.) which, with beautifully moulded Mullions (q. v.), became universal in the Decorated style. Windows of the Perpendicular style are marked by a departure from graceful flowing tracery and the introduction of vertical members. Horizontal bars or *transoms* are likewise freely introduced, and flat instead of arched heads are gradually adopted, until the W. becomes divided into a series of plain

Fan or Rose Window.

rectangular lights. Circular or rose windows with dividing shafts or mullions radiating from the centre are met with in Late Norman architecture, and many examples—for instance, in Lincoln Cathedral—remain to show the magnificence attained in their construction during the Early English and Decorated periods. See Sir G. G. Scott's *Lectures on Mediæval Architecture* (Lond. 1879).

Winds are currents of air which, produced by a disturbance of equilibrium in the atmosphere, tend by their motions to restore that equilibrium. Since the air is a gas acted on by gravity, it is evident that equilibrium must exist if the density throughout a level stratum is constant, and if the density diminishes with the height; and any cause which destroys these conditions must of necessity be followed by a mass motion of the air which is perceptible as a wind. The great source of all disturbances of equilibrium is the sun, whose heating action, by expanding a given region of air and so diminishing its density, causes an up-draught with a consequent overflow of air in the higher regions, and an in-draught of denser air from the surrounding regions. Although the first natural effect of heat upon a substance is to raise its temperature, yet, in the case of gases not confined in closed spaces, the observed effect consists more in an increase of volume with corresponding decrease of density. This expansion of air occurs mainly at the earth's surface, where the sun's radiant energy is rapidly absorbed and transformed in great part into heat, which acts upon the contiguous mass of air in the manner already described. Convection at once sets in, and the ascending mass of heated expanding air acting with like effect upon the air immediately above it causes an overflow of air at a higher region of the superincumbent column, thereby diminishing the barometric pressure at the locality where the action was started, and making conditions favourable for the generation of W. The Barometer (q. v.), indicating as it does the atmospheric pressure at any place and time, is invaluable in the study of the laws of W. A single barometer is, however, of small value, except for indicating the variation of pressure *in time* at a given place; for real scientific work its indications must be compared with the simultaneous indications of other barometers at surrounding regions. Thus only can the variations of pressure *in space*, which are the immediate cause of all mass-motions of air, be obtained. As already pointed out, the wind is the great restorer of the equilibrium, in virtue of the loss of which the existence of wind is possible. Hence it may be at once inferred that the wind always blows from a region of higher to a region of lower pressure; and thus a knowledge of the distribution of pressure over a given district of the earth's surface is sufficient to give a general idea of the direction and intensity of the W. at various points. This distribution of pressure is best shown by *isobaric* lines, or lines of equal pressure, each of which is drawn through all places at which the pressure has the value corresponding to that particular line. A series of such lines, each differing in value from its nearest neighbours by a certain definite amount, say 1-10th of an inch of barometric pressure, presents much the same appearance as the contour lines on the chart of a hilly country; and as, in the latter case, the closeness of the lines indicates the steepness of the slope, so in the meteorological chart the closeness indicates the barometric gradient, and where the barometric gradient is greatest there is the wind the most intense. The intensity of the wind is, of course, directly measured at any given station by means of the *Anemometer* (q. v.).

Though the solar heat is thus the original source of all wind action, that which mainly impresses upon particular W. their great characteristics is the earth's diurnal rotation. Thus in passing from the equator to the poles there is, generally speaking, a gradual diminution in the temperature of the air, and a corresponding increase in its density. Hence there must be a general drift of air along the surface of the earth from both poles towards the equator, with a simultaneous drift of air in the contrary direction in the upper regions of the atmosphere. But, because of the earth's rotation, a mass of air moving with a velocity equal to the velocity of the portion of the earth's surface with which it was originally in contact, will, as it drifts to lower latitudes where the velocity due to rotation is greater because the distance from the axis of rotation is greater, lag behind the earth in its motion from W. to E.—that is, the cold air which drifts towards the equator from each pole will appear to have an *easterly* set, while the upper current of equatorial air passing from lower to higher latitudes, and therefore from regions of greater to regions of smaller velocity, will, so to speak, shoot ahead of the earth, and therefore have a *westerly* set impressed upon it. This general atmospheric circulation is of course greatly modified by the configuration of land and water; but in the regions of the so-called *trade-W.* its character is well exemplified. These trade-W. are met with on both sides of the equator, but only at sea, the presence of land completely neutralising their action. Having, as already noticed, an easterly set—N.E. in the northern hemisphere, and S.E. in the southern—they are most characteristic in the western parts of the oceans where they abound. Beyond 30° lat. N. or S., the trade-W. cease, and variable W. prevail; while between the northern and southern regions of trade-W. occurs the region of calms, characterised by thick foggy air with frequent rains of short duration, attended with thunder and lightning. That such a region should exist may be inferred from the fact that for several degrees on each side of the equator the velocity of rotation varies but slightly with latitude, so that the eastern set of the indrawn air is correspondingly small. Meanwhile, co-existent with these constant trade-W. are the reversed upper currents, known as the *anti-trades*—setting towards the N.E. in the northern hemisphere, and towards the S.E. in the southern hemisphere—descending probably to the earth's surface in higher latitudes, and causing the S.-western and N.-western winds which prevail in the warmer regions of the N. temperate and S. temperate zones respectively. Coming originally from a tropical clime, these anti-trades descend to earth moisture-laden. Direct evidence for the existence of these reversed currents is not lacking. Thus when clouds do appear in the generally clear sky of the trade-wind region, they are observed to have a motion opposed to that of the trade-W.; while on the Peak of Teneriffe a strong S.W. wind is invariably experienced, though at its base the N.E. trade-W. reign supreme. The higher limit of the trade-W. varies considerably with the seasons. Thus, in the northern hemisphere, the northern boundary of the Atlantic trade-W. varies from 25° in winter to 32° in summer. In the vicinity of land, the trade-W. are much modified because of the local actions produced by the more rapid heating of land than water during the day, and its quicker cooling during night. Consequently, amid the coral islands of the Pacific, the trade-W. lose much of their characteristic traits. The so-called sea-breeze and land-breeze, which may be frequently observed in calm clear weather at a station near a sea-coast, give a fair notion of the nature of the modifications so produced. During day, when the land air is warmer than the sea air, a sea-breeze sets in towards the land. At sunset this breeze gradually dies down as the land cools, ceasing altogether when the land cools to the same temperature as the sea. After sunset, however, as the land continues to cool, a land breeze sets in, attaining a maximum and then gradually dying away as approaching morn reverses the conditions once more.

Consider now an area of low pressure situated anywhere on the earth's surface—a depression, or barometric trough, so to speak. The air flows in from all sides; but, in so flowing in, the currents from the equatorial side are deflected by reason of the earth's rotation towards the eastern margin of the depression, and the currents from the polar side towards the western margin, so that the result is a whirling or vortex motion of air round an axis passing more or less centrally through the depression. Such is the common characteristic of all storms, hurricanes, or cyclones, which are simply vortex-columns rotating in a direction contrary to the hands of a watch in the northern hemisphere, and in the same direction as the hands of a watch in the southern hemisphere. The deepest depressions originate in tropical regions, usually just within the outer limit of the trades, and the resulting storms recede from the equator with a marked westerly set, until, approaching the E. coast of obstructing continents, they are reflected towards the E., always of course receding at the same time from the equator. As the storm progresses, the vortex column usually dilates, with a corresponding decrease in its fury, though under particular circumstances contraction of the column may take place, with an accompanying increase of violence. In the N. Atlantic, the warm Gulf Stream very probably has a sustaining effect upon the cyclones which cause such havoc along the western coasts of Europe. The storms of the N. Atlantic have been the most fully studied of all, and they have been shown to travel from the equator in an approximately

parabolic path with the vertex towards America. During the last several years warnings have been telegraphed to this country regarding the approach of storms across this ocean, with a generally successful result, although not unfrequently a storm which has left America gets dissipated before it reaches our coasts. As a cyclone passes centrally over a region the barometer is extremely unsteady, falling to a minimum when in the heart of the depression, where, however, there is little or no wind. As the region is left behind it becomes exposed to all the fury of the wind, which now blows in a direction contrary to its original direction. At stations nearer the margin of the huge vortex a similar veering of the wind is observable. The size of these vortex columns varies considerably, from the grand mid-ocean cyclones of it may be 1000 miles in diameter to the small whirlwinds or waterspouts whose whole may be taken in at a glance. A knowledge of the laws of storms is invaluable to the navigator, who is thus better prepared to guide his vessel so as to avoid getting deeper into the hurricane; and for our present knowledge we are mainly indebted to the late Professor Dove of Berlin, who by marshalling fact and theory has firmly established the still barely formed science of meteorology upon its fundamental principles. An exceedingly ingenious theoretical conclusion first developed by Dove is his so-called Law of Rotation, which accounts for the recognised tendency of W. in the northern hemisphere to veer round from N. through E. to S. and on to W., while in the southern hemisphere the direction is altered. When the wind *backs*, *i.e.*, changes its direction in a manner contrary to this law, a depression or atmospheric disturbance of some kind is probably approaching. Instead of a depression, however, there may be an area of high pressure, a barometric crest as it were, which then forms the centre of an anti-cyclone or vortex column, whose direction of rotation is contrary to that of ordinary cyclones. Such an area of high pressure over Scandinavia was the immediate cause of the long-continued snow and frost which made so exceptional the winter of 1878-79 in western Europe. Anti-cyclones, however, have little of the fury of the cyclone, and no such evident translatory motion which characterises the latter. It has been impossible to touch upon more than the main features of wind action; for more detailed account the reader is referred to standard meteorological works, such as Sir John Herschel's *Treatise on Meteorology*, Buchan's *Meteorology*, or to Kaemtz's excellent manual. In Dove's original papers in *Poggendorff*, and Quetelet's memoirs in the *Annales de l'Observatoire de Bruxelles*, much suggestive matter is to be found. In conclusion, the statistical labours of Dr. Meldrum, the director of Mauritius observatory, into the periodicity of cyclones in the Indian Ocean, apparently coincident with the sun spot periodicity (see SUN), merit notice.

Wind'sor, the principal royal residence of England, and a municipal borough of Berkshire, is beautifully situated on the brow of a chalk hill overlooking the Thames, 23 miles W.S.W. of London by the Great Western Railway. It is properly called New W. to distinguish it from the decayed village of Old W., distant some 2 miles. The town has a handsome town-hall, 3 Dissenting chapels, 2 libraries, 2 hospitals, a dispensary, a grammar and other schools, infantry barracks, and a theatre. The Albert Institution, which is to comprise a great public bath, library, museum, &c., was founded 28th February 1879. It returns 2 members to Parliament, and publishes 2 newspapers. An iron bridge connects W. with Eton, the pinnacles of whose famous college are visible across the Thames. The great castle of W. stands on a steep chalk bluff to the E. of the town, and its buildings, covering 12 acres of ground, are girt on three sides by a terrace, which has a length of 2500 feet. It stands in the 'Little Park,' which is 4 miles in circumference, and is connected with the 'Great Park' (18 miles in circuit) by a grand avenue of trees. The Great Park lies S. of the castle, and further W. is W. Forest, with a circuit of 56 miles. The Norman keep, the royal house, and the chapel of St. George, crown Castle Hill, from which depending gardens and terraced slopes stretch away to a wide, wooded level, where rich corn land and pasture alternate with trim parks, open heaths, and forest glades. The district abounds in historical associations; the dripping wells bear the names of queen and saint, and the hoary oaks are entwined with legends. Shakespeare and Chaucer have a part in W. as well as Edward and Victoria, and almost as tangible as any historical fact are the mystery of Herne the Hunter, and the amours of the Merry Wives. By 'the winding shore' (from which is derived the name *W.*), stood a hunting-lodge as early as the time of Edward the Confessor. A legend which has not yet disappeared from the locality, ascribes the creation of this lodge to the semi-mythical King Arthur. The common story, however, is that William the Conqueror built the castle. But modern research shows not the slightest evidence of this, although William certainly inhabited the castle. There is no masonry of the 12th c. at W., and the earthworks, it is believed, were made in the time of Julius Cæsar or Caractacus. Removing his dwelling from the river's margin to the crest of the hill, Henry Beauclerc erected the First King's House, a pile which extended from the Devil's Tower to the Watch Tower, re-named Victoria Tower. Parts of Beauclerc's edifice remain in the massive walls of the Devil's Tower, &c. The Second King's House, the work of Henry of Winchester, brought within its lines Winchester Tower, and the whole curtain by Curfew and Salisbury Towers, round to Lieutenant's lodgings, now called Henry III.'s Tower. Although the house itself has long since disappeared, much of Henry's work remains, while to his successor, Edward of W., the upper ward owes its final shape. The lower ward Edward renounced entirely to the service of St. George, and here were built the Chapel of St. George, the College of St. George and the Canons and Poor Knights of St. George. Edward of York rebuilt St. George's Chapel on a larger scale, while Henry of Richmond, besides roofing the chapel, built a 'new tower' in the King's House, and constructed the first causeway to London. Queen Elizabeth erected the gallery which bears her name, and raised the great solid terraces above the Thames. The Norman Keep was raised in height by George IV., who also flanked the park entrance with Brunswick Tower, opened St. George's gate, and buttressed the north-east tower. Queen Victoria has attended rather to the slopes and gardens than to the castle; but during her reign the southern terrace has been opened, the work of restoration and repair has been effected diligently and reverently in cloister and chapel, and two railways have been brought to the castle gates. Since the days of Edward of W. the Castle Hill has kept its triple character, comprising the upper, middle, and lower wards, the bailies of the king, of the keep, and of St. George—'the residence of our sovereign, the symbol of our power, the altar of our saint.' Frogmore, the favourite residence of Queen Charlotte, and later of the Duchess of Kent, is half a mile from W. See Tighe's *Annals of W.*; Menzies, *History of W. Forests and Parks*; the *Transactions of the Archæological Society for* 1866 (paper on the Society's work in *Saturday Review*, 11th August 1866); and Hepworth Dixon's *Royal W.* (2 vols. Lond. 1879).

Wine (Lat. *vinum*; Fr. *vin*; Ital. *vino*; Ger. *wein*), a spirituous liquor produced by fermentation from vegetable substances containing saccharine matter. There are a great many vegetable substances from which, by this process, W. may be produced, such as apples, pears, currants, elder berries, and others; but unless otherwise expressed, the term is always used to indicate the fermented juice of the fruit of the common Vine (q. v.).

The history of the vine and its product goes back to the very earliest times of which there is any record, and it may almost be said that its use is coeval with the existence of man. In a very early part of the Mosaic record it is said, 'Noah began to be a husbandman, and he planted a vineyard, and he drank of the wine, and was drunken' (Gen. ix. 20); and throughout the whole of the Old Testament narrative, and in the prophetical books, there are frequent references to the use of W. and its effects. In mythological times Bacchus or Dionysos, the son of Zeus and Semele, is known as the god of W.; and the early Greek poets have sung its praises. Homer speaks of W. in its eleventh year; Horace commends W. which was of equal age with himself; and Pliny, who devotes to the subject an entire book of his work on Natural History, mentions some which he had tasted which was 200 years old. In more modern times the culture of the vine has been a matter of careful study and anxious observation, and so important has become everything connected with its proper growth and propagation and the most advantageous use of its fruit that the published works on the subject are said to number no fewer than 600.

In W.-producing countries the cultivation of the vine is as much a branch of national industry as that of wheat or other

food-producers is in others. The soils which are found to be suitable for its growth are very various in quality, but it thrives best along the borders of rivers or in places where a constant supply of water can easily reach its roots, as along the Rhine valley or in the paludal districts of the Gironde. It is usually propagated, not by seed, which takes five or six years before a seedling begins to bear, but by means of eyes cut from vines and planted in open beds and vineyards, or by planting cut canes which have been obtained from plants of the previous year, and which are usually not interfered with for three years after being put in the ground. The plants are placed in parallel lines, about a yard apart from each other, while the single vines are removed from each other by about the same interval. When the grapes are ripe they are collected and transformed into W. with no unnecessary delay. White grapes are crushed and pressed, and the juice, freed from stalks and husks, is put into clean barrels and allowed to ferment in a cellar or other temperate place. Black grapes, which are to yield red W., are crushed, put into vats, juice, husks, and all, and allowed to ferment until the W. is completed, and has extracted the colouring matter. The W. is then drawn off, the murk pressed, and the united products put into barrels. The process of fermentation, on which the peculiar property of the extracted liquor depends, proceeds spontaneously after the grapes have been crushed and the liquor extracted, and its action is to convert the sugar contained in the fruit into alcohol and carbonic acid. Effervescent wines, such as champagne, are bottled before the fermentation is quite complete, and in that way a portion of the carbonic acid which would otherwise have escaped is forcibly retained and dissolved in the W. The amount of alcohol contained in the W. varies in different sorts. In the stronger ports and sherries it amounts to from 16 to 25 per cent.; in hock, claret, and other light wines from 7 per cent. The greater part of the wines having more than 13 per cent. of alcohol (*i.e.*, 26 degrees of proof spirit) may be assumed to be brandied or fortified with spirit.

The obscure process of fermentation, by which the sugar of grape juice is changed into alcohol, has been the subject of a vast amount of investigation by many eminent investigators, the last and greatest of whom is Pasteur, who has published a most valuable work, *Etudes sur le Vin* (2d ed. Par. 1873). The change is induced by a minute fungoid organism, *Mycoderma vini*, and chemically it consists in transforming 105·4 parts of grape sugar (glucose) into alcohol 51·1 parts, carbonic acid 49·4, succinic acid 0·7, glycerine 3·2, and yeast matter 1·0. With these there are also developed minute portions of fusel oil and ether, to which is due the aroma or bouquet of the W. These ethers develop and interact while the W. is maturing, and as the value of a W. is entirely due to its richness in respect of these, the maturing and proper preservation of W. is a matter of the utmost importance. Other changes also occur during ripening. The acid tartrate of potash contained in the juice separates and forms a crust of Argol (q. v.); and frequently, especially with light wines, acid fermentation ensues, and the W. becomes sour. The acid fermentation is caused by a fungus, *Mycoderma aceti*, or by oxidation of alcohol by exposure. Other diseases of W. are due to parasitic and other growths, which have been traced by M. Pasteur. The varieties of W. produced are almost endless, and differ in every constituent according to the locality, season, and age; but generally the produce of each vineyard retains its own leading characteristics. In France, which stands pre-eminent as a W.-producing country, vineyards are found in almost every department; but the principal districts or centres round which the different classes of wines are grouped are Bordeaux, Burgundy, Rhône, Champagne, and the S. of France. The Gironde, of which Bordeaux is the centre, supplies the greater proportion of the light red wines we receive, and which are generally known under the name of clarets; and it includes several well-known districts, such as the Medoc, the Graves or Sauterne district, St. Emilion, and others. The Medoc furnishes the best wines of this part of France, and in the southern division are some of the most important vineyards. Among these are the famous names of Chateau Margaux, the property of a Spanish banker, the Marquis Aguado; Chateau Lafitte, the property of the banking-house of the Rothschilds; and Chateau Latour. The white wines of this district are generally known in England as Sauternes, among which is included the Chateau Yquem. The total annual produce of red and white wines in the Bordeaux district is estimated at about 90,000,000 of gallons. The name Burgundy is applied to the produce of the E. central districts of France most favourable to the cultivation of the vine, which also yield red wines of the highest quality. Among the most celebrated of these are Romanée Conti, Chambertin, Clos Vougeot, and La Tâche, all grown in the Côté d'Or, or 'golden hillside,' a low chain of hills extending from Dijon to Mâcon, on the Saone. The Rhône district is principally known in England from its production of Hermitage. Champagne is produced in several departments of France, including the Loire and the Jura, but the more important and valuable qualities are the produce of a district in the department of the Marne, part of the former province of Champagne. The best qualities are obtained only in the prefectures of Rheims and Epernay. The production of Champagne has increased enormously in our time. In 1835 only about 5,000,000 of bottles were exported from France; while in 1866 it had increased to no less than 22,000,000. Of the S. of France wines, that of Rousillon is the best known in this country. Of German wines, the most highly-esteemed are those which are produced on the banks of the Rhine, which have been aptly termed 'the gardens of the vine,' and the other most notable districts are those of the Mayn and the Moselle. The finer descriptions of Rhine and Mayn wines are generally known in England under the term Hock, although Hock, strictly speaking, is the produce of Hochheim, on the Mayn. With the exception of Assmannhausen, a red wine grown at Assmannhausen, a little below Rudesheim, the wines of Germany are nearly all of the white description. The best-known vineyards are those of Johannisberg, Steinberg, Marcobrunn, Rudesheim, Hochheim, and Raventhal. The district in which most of them are situated, known as the Rheingau, has attained a world-wide celebrity for its produce. The Johannisberg, which may be said to be the most famous of all, is a conical hill, projected from the Taunus Mountain, and rising about 150 feet above the level of the Rhine. It varies considerably in inclination, but the upper third, which is protected by the high castle from northerly and easterly winds, produces the best W. The property of this vineyard has frequently changed hands. At the time of the French Revolution it was in the possession of the then Prince of Orange, but it was taken from him after the battle of Jena, and given by Napoleon to Marshal Kellermann. In 1815 the Emperor of Austria took possession of it, and in the following year it was given to Prince Metternich, and still remains in the possession of his family. The preparation of the W. is carried through with the utmost care, and those bottles which are to be sent to a distance are packed with every precaution to ensure their safety. The brand of the Metternich arms is placed on each cork, and a label is placed on the bottle stating the name, year, and price of the W. which it contains. A well-known writer on wines says that 'a fine bottle of mature Johannisberg Castle is, by the fulness of its taste and the mass of its bouquet, the finest and most powerful drink on earth.' The finest vintages of Johannisberger sell for about 35s. per bottle, and secondary qualities are quoted at 24s. By some these wines are regarded as much overestimated. Of the same class generally with the wines of France and Germany are those of Hungary, which produces an excellent W. of a claret kind. Carlowitz is becoming extensively used in England as a light W. Tokay (q. v.) is the most famous of all Hungarian wines; and among vintages found in the British market may be mentioned Œdenburger, Somlauer, Ruster, Erlauer, and Ofener. These wines have from about 11 to 14 per cent. of alcohol, and possess the reputation of being somewhat rough. The produce of the Spanish Peninsula is of a different character from the wines already described, being generally of the descriptions known in this country as ports and sherries, the strongest of all kinds of wines, and at the same time the least natural; although in some districts natural unfortified wines of excellent quality are also produced in abundant quantity. Spain, as a wine-producing country, is generally divided into three sections,—the white W. or sherry district on the south-west coast, including the province of Cadiz; the red W. district in the north and north-east; and the sweet wine district in the south and south-east. In the first of these is situated Xeres, an important vine-growing district of many thousand acres in extent, which yields the best quality of sherry. The sherry and port imported to this country have an additional amount of alcohol, in the shape of grape spirit, put into them after fermentation in order to preserve them, and they are artificially sweetened. This adds considerably to their

strength, and gives it more body and keeping power than is possessed by the lighter natural wines. Malaga W. is a sweet luscious wine of great body, which is produced in the province of that name. The best-known port—the characteristic W. of Portugal—so far as concerns the English market, is Bucellas, which is said to have been made originally from transplanted Rhenish vines. Madeira, the produce of the island of that name, is a W. similar in character to sherry, and like it the various qualities are usually fortified by the addition of grape spirit. It is of great enduring quality, and is much improved by age and keeping. It is the practice to ship it to the E. or W. Indies, in order to bring it to proper maturity. Other varieties of W. are those of Marsala from Sicily, and Greek and Cyprian wines. Of Cape wines little comes to England in a natural condition; most of what is imported being used to produce strong brandied liquids in imitation of sherry and port. The Cape wines have not, however, a high reputation for delicacy or bouquet. Australian and American wines are not equal to those of Europe, and they yet occupy a very unimportant place; but their production is increasing, and they will no doubt improve, as they afford a cheaper and more natural beverage in those countries than wines which have been imported. The following return, made to an order of the House of Commons in April 1879, shows the number of gallons of French, Spanish, Portuguese, and all other foreign and colonial wines imported into the United Kingdom in the years 1859, 1873, 1875, and 1878, with the relative duties per gallon paid in 1859 and in the subsequent periods:—In 1859, of and from France, 1,010,888 gallons; Spain, 3,629,235 gallons; Portugal, 1,797,854 gallons; other foreign countries, 967,690 gallons, at a duty of 5s. 9 3-10d. per gallon; British possessions, 789,756 gallons, at a duty of 2s. 10 13-20d. per gallon—total, 8,195,513 gallons. In 1873, from France, 6,242,856 gallons; Spain, 9,389,367 gallons; Portugal, 4,037,594 gallons; other countries, 2,012,589 gallons—total, 21,682,356 gallons. In 1875, from France, 5,280,914 gallons; Spain, 6,891,738 gallons; Portugal, 4,478,097 gallons; other countries, 1,778,709 gallons—total, 18,429,305 gallons. In 1878, from France, 6,038,596 gallons; Spain, 5,714,948 gallons; Portugal, 2,920,285 gallons; other countries, 1,778,709 gallons—total, 16,452,538 gallons. For the three years last mentioned the following duties were levied:—Containing less than 26 degrees of proof spirit, 1s. per gallon; containing 26 and less than 42 degrees of proof spirit, 2s. 6d. per gallon; and additional for every degree of strength beyond the highest above specified, 3d. per gallon. A very exhaustive treatise *On the Origin, Nature, and Use of W.*, by Drs. Thudichum and Dupré, was published in 1872, and is now the authoritative text-book on wines and their culture.

Wings, the name applied to those organs in animals by which flight is effected. In their most typical development, as seen in birds, they consist of the bones of the fore-limbs, specially modified to form a support and axis, whilst attached to this skeleton are the muscles moving the limb. Externally the skin is provided with feathers, and the whole fore-limbs of the bird thus form the W.; while the bones of the shoulder girdle are modified to form a special support for the organ of flight. In the Bat (q. v.) the 'wing' consists of an expansion of the skin or integument, supported on four of the fingers, which are extremely long. This membrane, or *patagium*, extends from the fore limbs to the hind limbs, and in many cases between the hind limbs and tail as well. In such Mammalia as the flying foxes, flying squirrels, flying phalangers, and in the lizards known as flying dragons, the 'wing' is a mere expansion of skin, extending along the sides of the body, often connecting hind and fore limbs, and serving as a parachute to sustain the animals in their flying leaps from tree to tree, but in no sense serving as an organ of true flight. In insects the wing is formed of two delicate skin layers, supported on hollow tubes or *nervures*, placed in communication with the respiratory or breathing system. The W. of insects become thus related to respiration, and by their movements probably aid in the diffusion of air through the breathing-tubes.

Wink'elried, Arnold Struth von, a Swiss of Unterwalden, who, at Sempach, on the 9th of June 1386, contributed to the victory over Duke Leopold of Austria by rushing on the lances of the enemy and opening up a lane for his countrymen. A monument on the spot commemorates the deed. See Liebenau, *Arnold W.* (Aarau 1862); and Kleissner, *Die Quellen der Sempacher Schlacht und die Winkelriedsage* (Göttingen 1874).

Winneba'go, a lake of Wisconsin, U.S., in the basin of the Fox River. It is 26 miles long and 10 broad, and has an area of 212 sq. miles. Both the river and the lake are navigated by steamboats, and afford good fishing.

Winneba'goes, Winnipegoos', or Little Winn'ipeg, a lake of British N. America, draining into Lake Winnipeg, from which it is distant 50 miles westward. W. measures 125 miles by 25. It abounds in fish, and its shores are very fertile.

Winn'ipeg Lake, a lake in the province of Manitoba, British N. America, in the basin of the Saskatchewan (q. v.). It is 280 miles long from N. to S., and 60 miles in maximum breadth. Its area is 9000 sq. miles, and its altitude 710 feet above sea-level. Its chief tributaries are the Red River (q. v.) from the S., the Winnipeg from the S. E., Jack River and Behrens River from the E. Lakes Winnipigoos and Manitoba drain into it on the W. The Saskatchewan enters it on the N.W. and leaves it at the N.E. The lake is of varying depth, being very shallow towards the S. The E. coast is composed largely of Laurentian rocks; Silurian prevail towards the E. By the opening of a railway, 2000 miles long, towards the close of 1878, W. L. was brought into communication with New York.

Winn'ipeg River rises in Minnesota, U.S., and flows to Lake Winnipeg. Its course, though serpentine, is generally northwards. It passes through Rainy Lake and the Lake of the Woods, which are thus connected with Lake Winnipeg. Though its length is only 520 miles, it drains a very large basin, and discharges an immense volume of water into Lake Winnipeg. W. R. abounds in fish, and its shores are richly wooded, but the forest is rapidly being cleared, for the soil yields magnificent wheat crops. An Icelandic national colony has been founded, and a rapid influx of settlers from Britain is taking place. Much mineral wealth is known to exist in this region, though as yet it is undeveloped.

Winn'ipiseo'gee Lake (from *Winipisaukee*), a lake of New Hampshire, U.S. Its length is 25 miles, its breadth varies from 1 to 10 miles. Area 175 sq. miles; elevation above sea-level, 472 feet. It discharges by the Winnipiseogee River, an affluent of the Merrimac. It is studded with islands, and abounds in fish. The beautiful scenery of this district attracts many tourists.

Wino'na, a township of Minnesota, U.S., on the Mississippi, 90 miles S.E. of St. Paul by rail. It was founded in 1851, and has 15 churches, a public library, a normal school, 1 daily and 3 weekly newspapers. There are 3 saw-mills, 7 flour-mills, 2 foundries, and 6 carriage-factories. In 1874 it exported 5,550,000 bushels of wheat and $1,500,000 of lumber. Pop. (1875) 7192.

Win'slow, Forbes Benignus, D.C.L., born in London, but of a Massachusetts family, August 1810, was educated in Scotland and near Manchester, and after studying medicine at New York and the London University, passed the College of Surgeons (1835), and took his M.D. at Aberdeen. With his earliest practice he combined the duties of a *Times* reporter, but having since 1830 paid special attention to insanity, he opened a private asylum at Hammersmith (later another in London), and rose in time to be the supreme authority on all relating to diseases of the brain. Founder and editor of the *Quarterly Journal of Psychological Medicine and Mental Pathology* (1848) and of the *Medical Critic* (1861), vice-president of the Juridical and president of the Medical Society (1853), President of the Association of Medical Officers of Asylums (1857), and a Commissioner of Lunacy (1859), he was besides a member of numerous scientific bodies, a frequent contributor to the press, and the great 'expert' in medico-legal cases. He died at Brighton, 3d March 1874, having published *The Application of Phrenology to the Elucidation and Cure of Insanity* (1831), *Anatomy of Suicide* (1840), *Plea of Insanity in Criminal Cases* (1843), *Notes on the Lunacy Act* (1845), *Softening of the Brain* (1849), *Lettsonian Lectures on Insanity* (1854), *Obscure Diseases of the Brain and Disorders of the Mind* (1860; 4th ed. 1868), *Light, its Influence on Life and Health* (1867), &c.

Win'terbergen, a lofty mountain-range in the E. of Cape Colony, forming a part of the great dividing chain, sometimes

called 'the backbone of S. Africa.' Its culminating point, the Great Winterberg Peak, is 7806 feet high.

Win'ter Green (*Pyrola*), a genus of about 15 species of biennial or perennial herbs with evergreen leaves belonging to the natural order *Ericaceæ*. The white, pink, or yellowish flowers are generally arranged in one-sided racemes, and the fruit consists of a globose, five-angled capsule. They are distributed through the N. temperate zone, five species being natives of Britain, but all ranking as rare or local plants. None are of any economic interest.

Win'terhoek Mountains, a range in Cape Colony whose eastern termination is about 30 miles N.W. of Port Elizabeth (q. v.). Its loftiest peak, the Cock's-comb, is estimated to be 8000 feet high, and, though 20 miles inland, is visible 60 miles out at sea. There is also a W. Peak, 6840 feet high, 75 miles N.E. of Capetown, whence it is visible.

Win'ter Moth (*Cheimatobia brumata*), a species of Moth (q. v.) or *Lepidopterous* insect, the larvæ of which injure the leaves of plum-trees especially. It has a somewhat local distribution in England, attains a length of half an inch, and is of a light-brown colour. The male alone appears to be winged. The larvæ come out early in spring and devour large quantities of leaves. To protect plum-trees from their ravages the stems are coated with tar and grease.

Win'ter's Bark is the red-brown bark of *Drimys Winteri*, a tree, native of extra-tropical S. America, attaining in river-valleys a height of 60 feet. The name commemorates Captain Winter (one of the companions of Sir Francis Drake), who introduced the bark 300 years ago as an aromatic tonic. It is now seldom used, the W. B. of trade being the produce of *Cinnamodendron corticosum*, and nearly allied to Canella Bark (q. v.). See Tasmania.

Winter'thur, a town in Zürich, Switzerland, on the river Eulach, 38½ miles S.W. of Konstanz by rail, with hand silk-weaving, iron-founding, and manufactures of cottons, machinery, and locomotive engines. Pop. (1870) 9404.

Win'throp, a great American house, whose founder, Adam W., was born at the English town of Lavenham, Suffolk, 9th October 1498, grew rich as a London clothier, and in 1544 received a grant of the manor of Groton in his native county, where, after holding the mastership of the Clothworkers' Company (1551), he died 9th November 1562. His grandson, **John W.**, the 'Father of Massachusetts,' was born at Groton, 12th January 1581, studied at Trinity College, Cambridge (1602–4), and by his marriage (1605) acquired much outward estate and influence with the Puritans of the Eastern Counties. This led to his being chosen governor of the band of 900 colonists who, sailing from Yarmouth with eighteen vessels, landed at Salem 12th June 1630, W. during the voyage writing his *Modell of Christian Charity*. Settling at Shawmut (Boston), he became possessed of Governor's Island, still held by the W. family, and annually, with three exceptions, was re-elected governor down to his death at Boston, 26th March 1649. His fervent but tolerant piety, leader-like capacities, and liberal culture are reflected in his *Journal*, edited by J. Savage as *History of New England*, 1630–40 (2 vols. Bost. 1825–26; 2d ed. 1853), and well earned him the statue reared in the Federal Capitol by the State he founded (1876). See his *Life and Letters* by R. C. Winthrop (2 vols. Bost. 1864–67).—Son of the preceding by the first of four marriages, **John W.** was born at Groton 12th February 1606, and graduating at Trinity College, Dublin (1625), studied law at the Inner Temple. He served on the Rochelle expedition (1627) as attaché of the British embassy, visited Turkey (1628), and joining his father in Massachusetts was chosen a magistrate of the new colony (1633). Returning from a visit to England with a commission to found the new settlement of Saybrook at the mouth of Connecticut River (1633), he there raised a fort and acted as governor, his wife, a daughter of the 'regicide' Hugh Peters, removing from Boston to Pequit Harbour in 1645. On the union of Saybrook to Connecticut (1651) he became a magistrate of the latter colony, and as its governor (from 1651) obtained on a second visit to England (1661) a charter from Charles II. for the further incorporation of New Haven. He died at Boston, 5th April 1676, leaving in the *Transactions* of the Royal Society, of which he was an early member, proofs of his skill in physics and chemistry.—**Fitz-John W., F.R.S.**, born at Ipswich, Massachusetts, 14th March 1638, was bred in England and held a commission under Richard Cromwell (1658), but returned to Connecticut about 1670, and like his father was governor from 1698 till his death at Boston, 27th November 1707.—To the next generation belonged **John W., LL.D., F.R.S.** (1714–79), professor of mathematics and natural philosophy at Harvard from 1738, and author of able astronomical, as his son, **James W.** (1752–1821), was of theological works.—And in the present century come **Theodore W.** (1828–61), who falling at Great Bethel, in the first engagement of the Civil War, left several volumes of novels and essays, *Cecil Dreeme* (1861; 17th ed. 1864), &c.; and **Robert Charles W.**, sixth in descent from Governor John. Born at Boston, 12th May 1809, he graduated at Harvard (1828), studied law under Daniel Webster (1828–31), and was a Whig member of the Massachusetts legislature (1836–40), and of Congress (1841–50), filling in both assemblies the post of speaker. A United States senator (1850–51), he has paid two visits to Europe, has long been president of the Massachusett's Historical Society, and has spent many years at Brookline, near Boston, in lettered retirement, being author of *Addresses and Speeches on various occasions* (3 vols. 1853–78), a Memoir of Appleton (1861), *Washington, Bowdoin, and Franklin* (1876), &c. See W. H. Whitmore's *Notes on the W. Family and its English Connections* (Albany 1864).

Wire-Drawing is an art probably first practised in connection with the preparation of the fine strips or ribbons of gold and silver used in the manufacture of the rich gold and silver inwoven tissues which were largely made in Eastern countries. These strips, in ancient times, were cut from thin beaten plates; but in the early Christian ages the art of preparing drawn wires was first practised. The capacity of any metal for being formed into a drawn wire depends upon its ductility, and that property is greatest in gold, after which among the more familiar metals come silver, platinum, iron, copper, zinc, tin, and lead. The metals which are in practice employed are silver (with gold-plated silver for 'gold' wire), iron including steel, and copper with some of its alloys, especially brass. The manufacture of wire from these various sources, and its industrial applications, have enormously increased in recent years. The processes employed in the case of all metallic wires and the apparatus used are essentially identical, but the strength of the mechanism and the power applied necessarily vary with the gauge of the metal operated on. Taking iron wire as an example, the first process consists in preparing small circular rods of fine fibrous charcoal iron by passing it through suitable rolling-mills. These rods form the raw material of iron W.-D. The essential feature in all forms of W.-D. apparatus consists of the draw-plate, a plate of fine hard steel pierced with a regular gradation of punched holes of the various decreasing sizes, the gauge of which the wire is drawn. Through these holes of decreasing diameter the rod or wire is successively drawn, and when sufficiently reduced to form into a coil, it is wound on a revolving cone, the revolutions of which draw the wire through the holes in the fixed draw-plate. When dealing with rods or bars of considerable thickness in their first stages, they are drawn straight through the plate without attempting to coil or wind them up. In the process of reducing the wire to smaller gauges, the metal must be frequently annealed, and to protect it from the film of oxide which would thereby form on its surface, it is dipped into a scour bath of weak sulphuric acid and sulphate of copper, whereby it gets a thin protective coating of copper on its surface. For very fine wire, draw-plates jewelled with rubies or other precious stones are employed. Dr. Wollaston succeeded in obtaining wires of platinum and gold of $\frac{1}{30000}$ in diameter by coating bars with silver, drawing the composite bars exceedingly fine and dissolving off the silver; and in the same way steel wires of great tenuity have been prepared.

Wir'eker, Nigel, flourished in the 12th c. in the reign of Henry II. He was a precentor in the Benedictine Monastery at Canterbury, and a friend of William of Longchamp, afterwards Bishop of Ely, to whom he dedicated a treatise *On the Corruptions of the Church*. His chief work is *Brunellus*, or the *Speculum Stultorum* ('Mirror of Fools'), a satirical poem extending to nearly 4000 verses of Latin elegiacs. The hero Brunellus is an Ass who, convinced that he has an immense power of

patient labour, resolves to study at the University of Paris; he goes through the sciences, tries the various orders of the Church, is dissatisfied, resolves to establish a new one of his own, and after a long discussion with his favourite 'Galen,' is caught by his old master and forced to resume his original and true occupation. The poem is brisk and biting in its ridicule of scholastic and monastic follies, and may be regarded as in part a protest against ecclesiastical abuses.

Wire Ropes of iron or steel wire are now extensively employed in raising and lowering apparatus in coal-mines, as standing rigging for ships, as substitutes for chains in suspension bridges, and for telegraph cables. Endless W. R. are also used on traction railways, and in transmitting power over long distances where ordinary belting would prove unsuitable. Birmingham is the chief seat of the manufacture. W. R. were used in 1822 for a suspension-bridge at Geneva, and for a similar structure of great span at Freiburg in 1835. The earliest forms of W. R., known as *selvagee*, *formed rope*, and *flat rope*, have been almost wholly supplanted by the form known as *laid rope*, which is composed of strands of hard wires, usually six, laid spirally without twist around a core of hemp or wire, six of these strands being placed without additional twist around a hempen core. A variety of machines are in use for making W. R. The relative values of round ropes of iron, steel, and hemp are here tabulated :—

Hemp.		Iron.		Steel.		Breaking Strain.
Circumference.	Weight per Fath.	Circumference.	Weight per Fath.	Circumference	Weight per Fath.	
ins.	lbs.	ins.	lbs.	ins.	lbs.	tons.
5½	7	2⅛	4	1⅞	2⅝	8
7	12	2⅝	7	2⅛	4½	14
8	16	3⅛	9	2⅝	5½	18
9½	22	3⅝	13	3⅛	8	26
12	34	4⅛	20	3⅝	12	40

Wire Worm, a term applied to the larvæ or caterpillars of *Coleoptera* (q.v.), or Beetles belonging to the family *Elateridæ*. They are highly destructive to the roots of cereals, grasses, potatoes, and other plants. They moult thrice, and some are known to pass three years in their larval condition. From their long, slender, and cylindrical form, they get the name 'W. W.' The body is flattened at either extremity, and they have six legs and one anal proleg. Other names of the W. W. are 'Skip Beetle,' 'Click Beetle,' and 'Spring Beetle,' from its habit of jumping and springing when placed on its back, an effect due to the peculiar conformation of its chest-segments. The typical genus *Elater* has the front of the head of convex shape, and the chest is narrow at its anterior portion. The nearly-allied genus *Agriotes* also includes species of beetles, the W. W. larvæ of which are highly injurious to crops.

Wis'beach ('beach of the Wash'), a river-port of Cambridgeshire, England, stands on the Nene, 7 miles above its entrance into the Wash, and enjoys communication with the Midland, Great Northern, and Great Eastern Railways. Its church of SS. Peter and Paul, a large Early English and Perpendicular structure, has a double nave and a fine detached tower, the work most probably of Archbishop Morton; and there are also a town-hall (rebuilt and enlarged 1873), a spacious cattle-market (1869), a corn exchange, handsome Board schools (1879) in Early Pointed style, and a tabernacle cross by Sir G. G. Scott in memory of Thomas Clarkson (1877). Large sums have already been expended in improving the navigation and the construction of wharves, and since 1876 plans have been prepared for the formation of a floating-dock and altering the channel of the Nene, at a cost of £192,000. In 1878 there entered 448 vessels of 57,884 tons, and cleared 352 of 39,490 tons, while in 1877 the imports (chiefly timber and cereals) amounted to £352,808, the exports to £52,519. Brewing, tanning, iron-founding, and the manufacture of tobacco-pipes are among the industries of W., which publishes two newspapers. Pop. (1871) 9362. W. Castle, first mentioned in 1236, rebuilt by Morton, and now demolished, was the prison of Robert Bruce's wife, of Bishops Wishart and Watson, and of Catesby, Tresham, and other recusants. See the Proceedings of the British Archæological Society for August 1878, and Miller & Skertchley's *Fenland, Past and Present* (Wisb. 1878).

Wis'by, the chief town of the Swedish island of Gotland, is a thriving seaport on the W. coast, and has a fine cathedral (1200), and a pop. of (1875) 6314. It was once one of the richest of the Hanse towns, with 18 churches, but was taken and destroyed by the Danish king Valdemar III. in 1361, and has never regained its importance. There are great ruins of seven of its former churches; but of the others and of the castle of *Wisborg*, destroyed by the Danes in 1675, there is little trace left.

Wiscon'sin, one of the United States of North America, N. of Illinois and S. and W. of the Lake and State of Michigan. Area, 53,924 sq. miles, or 34,511,360 acres; pop. (1875) 1,236,729. Its surface is unbroken by any large mountains, but the tributaries of the Mississippi are separated from the affluents of Lake Superior by the low range of Iron Hills in the N.W., and from those of Lake Michigan by another watershed of small elevation. Nowhere do these hills exceed 1800 feet in height. The Wisconsin and Chippewa, tributaries of the Mississippi, are the chief rivers. The former is connected by a canal with the Menomonee, an affluent of Green Bay, Lake Michigan. Of many beautiful lakes the finest is Winnebago (q. v.). The geological formations include the Laurentian and Huronian in the N. centre, and various sandstones and limestones in the S.E. and W. The surface to the W. is covered by forest, and in the S. by extensive prairies. Wolves, bears, and deer are still found, but the buffalo, antelope, and wild turkey are extinct. The mean annual temperature of W. is about 42° F.; its summer is short and hot, its winter severe. The total amount of land under cultivation in 1870 was 11,715,321 acres, valued at $300,414,064. Its produce was valued at $78,027,032. This had probably increased to over $100,000,000 in 1875, in which year 24,784,000 bushels Indian corn, 18,436,000 wheat, 20,069,000 oats, 5,956,000 potatoes, 1,164,500 tons hay were raised. The live-stock were then valued at $54,733,803, and included 348,700 horses, 900,700 neat cattle (464,800 milch cows), 1,211,300 sheep, and 587,000 swine. The railway mileage in 1875 was 4875 but this is being rapidly extended. In the course of 1878, 83¾ miles were opened for traffic. The nationality of emigrants to this State is very varied. Germans, Welsh, Irish, and French abound. The principal towns of W. are Madison the capital, Milwaukee, La Cross, and Racine. W. was first settled in 1839, and was admitted to the Union in 1848.

Wiscon'sin River rises in Lake Vieux Desert, on the borders of Michigan and Wisconsin, U.S., and flows S. through deep pine-forests to Portage City, Wisconsin, where it becomes navigable, and from whence a short canal leads to the Fox River, then flows S.W. for 200 miles, joining the Mississippi 4 miles below Prairie du Chien. The breadth of the W. at its mouth is 1800 feet, its elevation is 600 feet, and its total length over 600 miles.

Wiscon'sin, University of, at Madison (q. v.), in Wisconsin, U.S., incorporated in 1838, opened its first classes in 1851. It comprises a school of ancient and modern classics; a school of agriculture, engineering, mining, and of general and military science; and a school of law (organised in 1868). Instruction is free to all natives of the state (of both sexes since 1867). In 1875-76 the U. of W. had 27 teachers and 345 students. The revenue, mainly drawn from land granted by Congress in 1838 (46,080 acres), in 1854 (46,080 acres more), and in 1866 (240,000 acres more), and augmented both by State appropriations in 1870 and 1875 to the amount of $170,000, and by an annual tax (levied since 1876) on the total valuation of the State, is now about $40,000.

Wise, Henry Alexander, an American statesman, was born at Drummondtown, Virginia, December 3, 1806, graduated at Washington College, Pennsylvania, in 1825, sat in the Baltimore Convention of 1832, where he advocated the nomination of General Jackson for President, but opposed that of Van Buren for vice-president, opposed nullification, was elected to Congress in 1833, and re-elected successively each year until 1843, when he was nominated minister to France by Tyler (q. v.), whose election as vice-president he had promoted. The Senate refused to confirm his appointment, but allowed him to be sent as minister to Brazil in 1844. In 1847 he returned to his native country, and took part in the Presidential election of 1848. In 1850 he was a member of the Reform Convention of Virginia, and in 1855 was

elected Governor of Virginia after an arduous canvass against the 'Know-Nothing' party. In this capacity he signed the death-warrant of John Brown (q. v.) in 1859. Though opposed to secession, in 1860 W. followed his State, and during the Civil War held the commission of a brigadier-general. Since the war he lived a private life at Richmond, where he died, September 12th, 1876.

Wise'man, Nicholas Patrick Stephen, Cardinal, was born of Anglo-Irish parentage at Seville, Spain, 3d August 1802. Brought by his mother to England at the age of five, he first was placed at a school in Waterford, and next at Ushaw, whence after close upon eight years' study he passed to the English College at Rome (1818). Here he found a fast friend and patron in Leo XII., graduated D.D. (1823), received priest's orders (1825), and two years later was made Professor of Oriental Languages in the Roman University, becoming also vice-rector, and in 1828 rector, of the English College. As such he extended in 1832 a generous welcome to Lamennais and Montalembert, no favourites of Gregory XVI., and delivered his lecture on the *Connection between Science and Revealed Religion* in 1835, the year of his return to England. His founding with O'Connell the *Dublin Review* and controversy on the Real Presence with the Bishop of Ely were followed by his appointment to the presidency of Oscott and consecration at Rome as Coadjutor of the Midland District (1840), on which occasion he induced the Pope to augment the number of English Vicars-Apostolic. His hopes for the conversion of England, fostered by the spread of Tractarianism, by an Act of Parliament authorising diplomatic relations with Rome, and by his interview with Lord John Russell, led him to urge on Pius IX. the re-establishment of the Catholic hierarchy during two visits to Rome, in 1847–50, between which visits he rose to be pro-vicar and vicar-apostolic of the London District. But returning in 1850 as Archbishop of Westminster and the first cardinal in England since Pole's death, he found himself met by Russell's *Durham Letter*, a cry of 'Papal Aggression,' and the Ecclesiastical Titles Bill (q. v.). Stillborn as was this Act itself, it influenced W.'s later years, which, save on the rare occasions when he still lectured at the Royal Institution, were wholly passed in the diligent discharge of his episcopal functions, and in company where his princely rank remained unchallenged. He died in London 15th February 1865. His works, somewhat too ornate for an English taste, are widely read upon the Continent; they include *Horæ Syriacæ* (1828), *The Real Presence* (1836), *Lectures on the Doctrines and Practices of the Catholic Church* (2 vols. 1836), *Three Lectures on the Catholic Hierarchy* (1850), *Essays on Various Subjects* (3 vols. 1853), *Fabiola, or the Church of the Catacombs* (1855), and *Recollections of the Last Four Popes* (1858), some of which in their German form had reached by 1878 a 4th, a 6th, even 11th edition. A graceful tribute is paid to the Cardinal's learning, virtues, justice, and sweetness of disposition in Lord Houghton's *Monographs* (Lond. 1873).

Wish'art, George, one of the earliest martyrs for the Protestant faith in Scotland, belonged to a good family in Kincardineshire, and was born early in the 16th c. He was educated at the University of Aberdeen, whence he proceeded to France and Germany, where he probably imbibed the doctrines of the Reformation. On his return to Scotland, he commenced the study of Greek at Montrose—the first town in his native country where that language was publicly taught. Becoming a teacher of the new tongue, he was summoned before the Bishop of Brechin on a charge of heresy, for having put into the hands of his scholars the Greek New Testament, and in consequence withdrew for safety to England in 1538. Here he entered himself at Bennet, or Corpus Christi College, Cambridge, where he lived for six years. In 1543 he went back to Scotland, and soon attracted great audiences by the eloquence of his preaching and the exalted piety of his character. At Montrose, Dundee, Ayr, Galston, Mauchline, and other places, he boldly and fervidly proclaimed the gospel message, exciting the enthusiasm of his friends and the rage of the priests. In December 1545 he arrived in Leith, in answer to a request from his Ayrshire friends to meet them in Edinburgh and defend himself before a convocation of the clergy. Here he preached, having among his auditors Knox and many of the Lothian gentry. Thence he proceeded to Inveresk, Tranent, and Haddington, haunted with the conviction that his end was near. Arrested in the house of Cockburn of Ormiston by the Earl of Bothwell, he was brought to St. Andrews, where he was tried by a clerical assembly, and condemned to death as an obstinate heretic. On the 1st of March 1546 he suffered at the stake on Castle Green. Within three months his proud persecutor, Cardinal Beatoun, was assassinated. There is evidence that this violent deed was planned some time before the death of W., and that a certain 'Wysshart' was privy to the design, and had an audience with Henry VIII. on the matter. So much is clear from the Hertford and Sadleir 'State Papers.' The Scotch gentry by whom this 'Wysshart' was deputed were the martyr's friends; and it is difficult, except on *à priori* grounds (which are, of course, unsatisfactory), to resist the conclusion that the gentle and mystic enthusiast was no more averse to the 'killing of the cardinal' than Knox himself would have been. See Foxe's *Book of Martyrs*, Knox's *History of the Reformation*, M'Crie's *Life of Knox*, Burton's *History of Scotland*, and Cunningham's *Church History of Scotland*.

Wis'mar, a seaport of Mecklenburg-Schwerin, Germany, situated at the S.E. end of a bay which forms a safe and commodious harbour, 18 miles N. of Schwerin by rail. It contains several fine edifices, especially the Gothic Marienkirche (1339), the Nicolaikirche, the Heiligegeistkirche, the Fürstenhof (1554), now the seat of the municipal authorities, the Rathhaus, and the theatre (1842). W. has fisheries, iron-founding, and manufactures of chicory, tobacco, beer, brandy, and essences. In 1871 there entered its harbour 264 vessels, and cleared 260 of 16,265 tons. The chief article of export was wheat to England, and the chief imports were—from England, coal, iron, fire-proof stone, cement, and earthenware; from Sweden, timber and iron; from Lübeck, general wares; and from Prussia, timber, tiles, cheese, &c. Pop. (1875) 14,471.

Wiss'embourg (Ger. *Kron-Weissenburg*), a town of Lower Elsass, on the Lauter, 41 miles N.N.E. of Strassburg by rail, has a Gothic abbey church of SS. Peter and Paul (13th c.), with a tower and cloisters, an evangelical church, and a gymnasium. It manufactures hosiery, paper, hats, and leather, and carries on brewing, dyeing, and considerable trade in wine. Pop. (1875) with the garrison (two battalions of infantry) 6152 (3613 Evangelicals). W. owes its existence to an independent Benedictine abbey, which was founded in the 7th c. and secularised in 1534. The town, dating from 1247, was one of the ten free-towns of the Empire in Elsass. It suffered severely during the Thirty Years' War, was in 1677 sacked by the French, and in 1697 annexed to France. It was fortified by the French in 1746. At W., on August 4, 1870, the Prussians and Bavarians under the Crown Prince gained their first great victory over the French under Douay. The Germans lost in the action 91 officers and 1460 men [illegible] and wounded; and took 4 mitrailleuses, 22 guns, and 10[illegible]oners.

Wista'ria, a genus of *Leguminosæ*, [illegible]s of N. America, China, and Japan. The leaves are pinnate, the flowers are arranged in axillary and terminal racemes, and are succeeded by leathery pods. In the two species in common cultivation, namely, *W. frutescens* and *W. chinensis*, the lilac-coloured flowers are produced in a profusion of pendulous bunches. The first is indigenous in the United States, and the other of Eastern Asia. Both are frequently grown against sunny walls, and can be trained to extend over a large area, when they are strikingly ornamental.

Witch'craft is often defined as a survival of paganism, but the definition, if not indeed erroneous, is certainly incomplete, as it fails to account for the W. of non-Christian races. Take, for example, the widespread superstition that one can hurt an enemy by moulding an image of him in wax and melting it before a fire, or piercing it with pins; the charm belongs as little to any heathen as it does to the Christian faith. It was an act of sorcery pure and simple alike when practised by the Italian peasant of Virgil's day (*Ecl.* viii.), or by the ladies forming the Nizam of the Deccan's harem early in this the 19th c., and when Margery Jourdain, the cunning witch of Eye, employed it against the life of Henry VI. Again, if W. be merely paganism lurking in disguise, how is it that we find the very pagans persecuting its votaries to the death—the Roman decemvirs making it a capital offence, and at Athens a witch named Lemia executed in the lifetime of Demosthenes? The difficulty vanishes before the theory of one of the latest and ablest investigators of

the subject, Mr. A. C. Lyall. He maintains that 'from the very outset there has been a radical separation between W. and the humblest form of religion, that W. is the aboriginal and inveterate antagonist of religion or theology, and hardly less so in the most primeval ages of barbarous superstition than it was in the days of King James I.' The underlying principle of all religions, even of Fetishism (q. v.), is that man by himself can do nothing, but W. is grounded on the belief that certain men possess certain abnormal powers, which they can exercise without the intervention of a deity. It was the world-old story of knowledge making men as gods. The earliest savage Prometheus who stole fire from heaven—in other words, discovered that by the friction of two sticks he could produce a flame—would be apt thenceforth to omit to pray for fire; and his untutored mind, ignorant of the true relation of cause and effect, might leap to the conclusion that he who was able thus to command the fire should also be able to call down rain. Children in the western counties of England still fancy that if they see a rainbow in the sky and set two sticks crosswise, the colours will presently fade away; and so indeed they do. Similar experiments have doubtless proved no less satisfactory to many a primeval meteorologist, who to himself and his neighbours would seem, like the wife in the German *mährchen*, a kind of ruler of the universe. Medicine, too, opened up a boundless field for mingled knowledge and credulity. If now-a-days the inventor of a patent pill, which possibly is good for a single ailment, dares vaunt its efficacy in every known disorder, assuredly the first chance discoverer of simples to cure an ulcer or a toothache would be tempted enormously to magnify his simples' and his own abilities, and admiring patients would ask themselves whether he who could heal could not also inflict disease. The latter notion would be sedulously fostered by priests, whose mediatory trade was spoilt by another's pretensions to independent power, and who, while claiming the credit of every blessing for their gods, would cast the blame of all untoward accidents on such a worker of unlicensed miracles. At first the outward difference between a sorcerer and the priest of a barbarous creed would seem as slight as between Messrs. Maskelyne and the Davenport Brothers. Each would perform the selfsame tricks as his rival, but the priest would ascribe them to the deity working through him, the sorcerer to his own occult arts. And these would bring him no small profit, since everywhere and at all times man, when heaven denies its help, has been ready to have recourse to inferior aid—a truth brought out in the Virgilian line, '*Flectere si nequeo superos Acheronta movebo*,' and in the history of Saul, who, having inquired of the Lord and received no answer, sought counsel from the witch of Endor. A principle, moreover, of fetishism and polytheism being Live and let live, he would be safe from persecution on abstract religious grounds, though jealousy, fear, and resentment might expose him to instant peril of his life. 'The magician,' says Lecky, 'was punished because he injured man, and not because he offended God;' and to support this opinion he adduces the stringent edicts passed at Rome against casting the horoscope of the reigning emperor as a practice tending to promote conspiracies, though at the time divination formed part of the Roman religion. But measures against a reputed sorcerer might receive a religious tincture by priests being called upon to aid in his detection through Ordeals (q. v.), which everywhere present a strange identity, those of water and heat being equally familiar to the modern Indian witch-finder and to the mediæval inquisitor. Another curious point of resemblance between the Eastern and Western systems of W. is that suspicion generally fell or falls on women, and 'such women commonly,' adds Reginald Scot, 'which be old, lame, bleare-eyed, pale, foul, and full of wrinkles.' A reason commonly given for this preference, that conception of Catholic celibacy which drew from the Fathers such fierce invectives on the female sex, fails in the case of non-Christian lands; dislike of ugliness was, therefore, the most probable cause. Such is an outline of early W.; which presently assumed a quasi-religious character, since the wizard, to keep abreast of the priest, would find it necessary himself 'to claim a backstairs interest with deities,' so would patronise some ill-conditioned god, only making him serve as a familiar instead of paying him service. Thus the original antipathy between religion and W. subsisted, but in a somewhat modified form; and the memory of the real origin of W. (a smattering of science) was preserved in many of the names of W. and its practitioners —Eng. *wise man* or *woman* and *wizard*;* Russ. *vyêd'ma*, 'witch,' from *vyedat*, 'to know;' Gael. *fiosachd*, 'sorcery,' from *fios*, 'knowledge,' &c.; just as the awe felt for all science by the vulgar expressed itself in the Lat. *mathematicus* ('astrologer') and the Fr. *grimoire* ('a grammar or book of magic,' whence *gramary*), and in the ascription of Magic (q. v.) to the reputed inventors of gunpowder, printing, and the like.

Alone of all the ancient faiths Judaism had from the first sternly discountenanced W., the Law including in one sweeping condemnation all workers of hidden arts—diviners, augurers, fabricators of charms, and necromancers. As monarchies are always more jealous of their rights than republics, so monotheism could not but look on the claiming of godlike powers by men as an infringement of the One God's attributes, as a 'sin of rebellion,' to be punished as such; and this feeling increased in intensity and was extended in its application with the growth and spread of Christianity, whereby mankind was split into two hostile camps. For as the number of malcontents increases if once a rallying-point be granted them in the person of some arch-rebel or dethroned sovereign, so witches multiplied, or were believed to multiply, thanks to the Christian concept of a Devil (q. v.). The whole heathen world was assigned him for a realm, the ancient divinities were branded as cacodæmons, and to the early Christian the earth seemed so replete with evil spirits (afterwards estimated at 7,405,926 in number) that the Messalians of the 4th c. A.D. even made spitting a religious exercise, hoping thereby to cast out the devils they inhaled. The belief, moreover, that each human soul is an individual entity, to be saved or lost, led to the grosser notion that man, by a kind of *post-obit* compact, might purchase power and satisfaction in the present world at the price of eternal torment in the next; and so early as the 6th c. one hears of Theophilus, coadjutor-bishop of Adana in Cilicia, signing away his soul to Satan, but cheating his creditor with the Virgin's help. Eutychianus' Greek version of this legend found its way into western Europe, where the nun Hroswitha cast it into a Latin drama in the 10th c., as in the 13th Rutebeuf did into a French miracle-play; and the type thus struck, and further embellished with a species of feudal homage to the Fiend, became a pattern for innumerable later tales, one of which even attached itself to the name of a Roman pontiff, Sylvester II. Another widespread superstition was that demons, both male and female (*incubi* and *succubi*), made mortals the objects of their passion; 'this fact it were impudent to deny,' said St. Augustine, who himself saw a satyr. The fears inspired by such doctrines may easily be conceived, and when the Church obtained political ascendancy, her earliest efforts included measures against W., paganism being still too strong to be safely assailed. Soon after his conversion (306), Constantine the Great condemned to the flames any aruspex who should perform his rites in a citizen's house; and the persecution, which with occasional breaks lasted for upwards of seventy years, had a powerful influence on the subsequent history of W., by forming a mass of tradition that placed the reality of the crime beyond a doubt. In 385 Priscillian, a Spanish bishop, was executed at Trier for sorcery; towards the close of the 6th c. great numbers of women were burnt or broken upon the wheel for slaying Fredegunde's son by spells; and many wizards suffered under new edicts of Karl the Great. But for six hundred years witch-trials were comparatively rare, lay superstition proving its own antidote in days when fear of demons was equalled by unquestioning faith in relics and holy water, whilst the clergy as masters of the position found few heresiarchs to brand with sorcery. First the heretical movements of the 13th c. disturbed the Church's calm; next the Black Death (q. v.), attended by the Flagellant and dancing manias, aroused the popular mind to a dread conviction of Satan's agency. Small wonder that some poor rebel souls transferred, as they deemed, their fealty to this all-powerful master, and shared for reward the fiery death of scores upon scores of innocent victims to the universal panic. At Carcassonne in Languedoc alone over 200 persons were condemned during 1320-50, and from this period the prominence of 'Witches' Sabbaths' dates. Not that belief in such unholy gatherings was new, since Psellus,

* *Witch* (O. Eng. *wicce*) has itself been often derived from the Old Eng. *witan* (Ger. *wissen*, 'to know'), but is more probably akin to the Gothic *veihan* (Ger. *weihen*), 'to do or consecrate,' in which case it may be compared with the Ger. *zauberer* (O. H. Ger. *zouwan*, 'to make'), the Ital. *fattucchiero*, 'a sorcerer' (Lat. *facere*), &c.

in the 11th c., had described how 'certain magical heretics, to wit the Eutychians, assemble themselves every Good Friday at night, . . . and cutting their children in pieces, fill pots with their blood, then burn the carcases, and mingle the ashes therewith, and so preserve the same for magical rites' (Scot). But floating traditions concerning the secret conventicles of persisting or relapsed pagans and heretics were now first gathered together; now first we read of witches riding through the air on broomsticks or by the virtue of magic salves, of their feastings, dances, and songs, their sacrifices of dogs, cats, and unchristened babes to a goat-shaped fiend, and of many other unhallowed rites, all stereotyped in the *Malleus Maleficarum* (1489) of the German inquisitors, Krämer and Sprenger. These worthies' appointment was due to the Bull *Summis Desiderantes* of Innocent VIII. (1484), and under them commenced that German reign of terror which cost 7000 lives at Trier, 600 at Bamberg, and 900 at Würzburg—atrocities rivalled by 1000 executions in the Italian province of Como within a twelvemonth, 400 at Toulouse in a day, 500 at Geneva in three months' time, &c. The madness seized upon all nations and all estates of men, alike on Catholics and Protestants, and often on the accused as firmly as on their accusers, so that 'for the most part,' says Lecky, 'the trials represent pure and unmingled delusions.' As Mohammed had ascribed his rheumatism to the magical practices of enemies, so Luther looked on his earache as 'peculiarly diabolical,' and exclaimed of witches, 'I would burn them all.' England by its insular position and intense political life was longest preserved from the infection; and Jean Darc, noblest of all the delusion's victims, died on French soil and under a French bishop's sentence, although by English hands. But slumbering superstitions awoke in the tumult of the Reformation, and we find Cranmer's articles of visitation bidding the clergy make inquisition for 'any that use charms, sorcery, enchantments, W., soothsaying, or any like craft invented by the Devil.' The earliest formal statute was passed in 1541, and this and succeeding laws long remained milder than those of Continental states, witches accused of murder being sentenced to the gallows, not the stake, and their less guilty sisters to the pillory and imprisonment only, while pricking, swimming, and deprivation of sleep were gentle tortures compared with those prescribed by Bodin in his *Demonomanie des Sorciers* (1587). James VI., himself the author of a dialogue on *Dæmonologie* (1597), carried to England the sterner Scottish 'Actis anentis W.,' and in the first year of his reign a parliament, including Coke and Bacon, doomed witches to death on a first conviction, even though they should have abstained from injury to their neighbours. His cruelties, however, against the Lancashire witches were wholly eclipsed during the Commonwealth, in whose brief term of power over 3000 sorcerers are said to have perished, and chiefly in the Presbyterian Eastern Counties. At Bury-St.-Edmund's sixty were hanged together in 1646, 'among them an old reading parson, who confessed that he had two imps,' as Baxter with evident complacency remarks in his *World of Spirits*. There also, twenty years later, sentence was passed upon two Lowestoft witches by the benevolent Sir Matthew Hale, who upheld the existence of W. as well by the Scriptures as by the laws of England and other lands; while the author of *Vulgar Errors*, Sir Thomas Browne, complained how 'the Devil in these cases did excite such humours superabounding in men's bodies, whereby he did afflict them with distempers, co-operating with the malice of those we call witches.' And from Suffolk the gloomy delusion passed to the New England settlements, Governor Winthrop (q.v.), whose eldest son himself dabbled in alchemy, presiding at the conviction of Margaret Jones, of Charlestown, in 1648. She was the first of more than forty victims, the last and most famous of whom were the twenty Salem witches (1692), nineteen of whom were hanged, while one, an old man of eighty, was pressed to death. In this 'New England tragedy,' the most notable points were the action of Cotton Mather (q. v.), by Lowell and most authors accused of having with other Puritan divines blown superstition's dying embers into a flame, but defended by Mr. Poole, and the fact that all the accused died protesting their innocence with unshaken constancy. In Scotland there can be hardly any question that, under the influence of Presbyterian fanaticism, W. assumed the vastest proportions and most malignant character. Elsewhere the superstition was largely mixed with imposture; here it was wholly undiluted. Its outbreak followed close upon the Reformation, the earliest law being passed in 1563; and throughout its entire course a spiritual terrorism was fostered, upheld, and protracted by the Scottish clergy, the divines of the Associated Presbytery declaring as late as 1773 their belief in W., and deploring the reigning scepticism. Boxes were set in the churches to receive the accusations, and from their pulpits the ministers denounced suspected persons by name, forbidding anyone to shelter them. In all, 4000 victims are thought to have perished, among them 30 women who were charged with having raised a tremendous storm to sink the ship that was bringing James VI. and his bride from Denmark (1590). The last judicial execution for W. in Scotland took place at Dornoch in 1722, in England at Huntingdon in 1716, in Germany at Landshut in 1756, in Spain in 1780, and in Switzerland at Glarus in 1782. And from the cessation of executions most writers infer that belief in W. has utterly passed away—an inference hardly borne out by facts. Leaving aside such out-of-the-way regions as the Ukraine, where, according to Ralston, each hamlet still keeps its witch, we will confine ourselves to England, and single out a few of the witch cases of the last twenty years. In 1865 a poor old paralysed Frenchman died in consequence of having been swum as a wizard at Castle Hedingham, Essex; in 1875 the trial at Warwick Assizes of the murderer of a reputed witch brought out the fact that over one-third of the villagers of Long Compton were firm believers in W.; and in April 1879, at E. Dereham, Norfolk, a man was fined for assaulting the daughter of an old woman who had charmed him by means of a 'walking toad.' At the present time the writer knows of at least four 'wise men' in Wales, who thrive on the fees they receive from their dupes, and the infamous nature of whose dealings strongly corroborates Mr. Lyall's verdict that, 'if we may judge by study of its practices from real life in India, our ancestors may have had very good reasons for persecuting W., though they proceeded on grounds widely mistaken, and very often against the wrong persons.' W., however, save in the guise of Spiritualism (q. v.), has ceased to form an article in the creed of all educated people, excepting a few such eccentric spirits as the late Vicar of Morwenstow, R. S. Hawker (died 1875). That Wesley was right in saying that 'giving it up is in effect to give up the Bible,' few would allow; had he for 'Bible' substituted 'Devil,' he had shown a clearer perception of the true causes of one of the greatest revolutions in human thought—a revolution wrought, not by the fresh exposure of a delusion sufficiently exposed by Wier and Scot, but by the steady, imperceptible spread of 'Scepticism.' See Johann Wier, *De Præstigiis Dæmonum* (Basel, 1563); Reginald Scot, *The Discouerie of W.* (Lond. 1584; 2d ed. 1651); Glanvil, *Sadducismus Triumphatus, or Full and Plain Evidence concerning Witches and Apparitions* (Lond. 1689); Sir G. Mackenzie, *A History of the Witches of Renfrewshire* (1678; new ed. Paisley, 1878); Haas, *Die Hexenprocesse* (Tüb. 1865); W. F. Poole, *Cotton Mather and Salem W.* in the *North American Review* for January 1869; A. C. Lyall, *W. and Non-Christian Religions* in the *Fortnightly* for April 1873; besides works cited under MAGIC, VAMPIRE, WERWOLF, and in Buckle's *History of Civilisation in England* (new ed. Lond. 1867), Lecky's *History of Rationalism* (5th ed. Lond. 1872), Lowell's *Among my Books* (Lond. 1870), Tylor's *Primitive Culture* (Lond. 1871), and M. D. Conway's *Demonology and Devil Lore* (2 vols. Lond. 1879).

Witch' Hazel (*Hamamelis virginica*), a shrub of 6–12 feet high, native of woods from Canada to Florida, bearing axillary clusters of yellow flowers, which are produced during a great part of the winter. Its seeds contain a quantity of oil and are edible, while the bark and leaves are astringent. The W. H. has been long in cultivation as a garden ornament. The natural order *Hamamelidaceæ*, or the W. H. family, includes 17 genera of deciduous shrubs with alternate leaves and small axillary flowers, found in N. America, Africa, and Asia, but not represented in the European flora. The name W. H. is said to be derived from the supposed virtue of the above-mentioned species as a divining-rod.

Wit'enagemot'. See PARLIAMENT.

With'er, George, an English poet, the only son of George Wither, a landed gentleman, was born at Brentworth, near Alton, in Hampshire, June 11, 1588. From the grammar-school of Coleman W. passed in 1604 to Magdalen College, Oxford, and

after spending some little time at home 'at the plough,' he went to London and entered himself fellow of Lincoln's Inn. A satire, *Abuses Stript and Whipt*, which he published in 1613, led to his imprisonment in the Marshalsea; but his *Satire to the King*, supported, it would appear, by the friendship of the Earl of Pembroke, secured his release in the following year, and in 1622-23 he obtained the king's patent for his *Hymns and Songs of the Church*. In 1632 we find him in the Netherlands, and in 1639 he served as captain of horse in the expedition of Charles I. into Scotland. Three years later he raised a troop of horse for the Parliament; and though he was taken prisoner by the royalists, they were, if not generous enough, at least facile enough to set him free on Sir John Denham's plea that while W. lived Denham was not the worst poet in England. From the Parliament he afterwards received numerous favours, culminating in the mastership of the state office in 1655 and 1656; but on the Restoration his property was confiscated, and he was once more cast into prison. Released in July 1663, he only survived till May 2d, 1667. W. is one of the most voluminous of poets; upwards of a hundred separate publications are enumerated by his bibliographer. The greater part has little permanent worth, though he almost always wrote good simple honest English; but ever and anon we come upon poems or passages that are the very perfection of artless art. Damned by Pope as the 'wretched W.,' he has in more modern times received the praise of Brydges, Hallam, Southey, and Lamb. Among his more important productions are *The Shepheard's Hunting* (1615), a pastoral; *Britain's Remembrancer* (1627), *A Collection of Emblemes* (1635), and *Hallelujah, or Britain's Second Remembrancer* (1643). See Willmott, *Lives of the Sacred Poets*; and Farr, Introduction to his edition of the *Hallelujah* (Lond. 1857).

Wit'ness. See EVIDENCE, LEGAL. CIRCUMSTANTIAL EVIDENCE. One credible W. is sufficient legally to prove any single fact. A W. may not read his evidence, but he may refer to memoranda made by himself at the time when the fact to which he testifies took place. A W. on whom a Subpœna (q. v.) has been served, failing to appear at the trial, forfeits £100 to the Queen and £10 to the aggrieved party, besides being liable in damage to the value of any loss caused by his absence. But a W. in a civil case is not bound to attend a trial unless his expenses are tendered to him. Daily allowances to witnesses range from 5s. to subordinate mechanics or out-of-door labourers, to £1, 1s. to professional men, who are paid according to time employed. Men of business who are not so paid, and non-professional gentlemen, are only allowed a reasonable sum for necessary expense.

Wit'ney, a market-town of Oxfordshire, England, on the Windrush, 13¾ miles W.N.W. of Oxford by rail, has an interesting 13th-c. church (restored 1867), a staple or blanket hall (1721), town-hall (1863), and county court-house (1859); publishes one weekly newspaper; and besides its celebrated manufacture of blankets, has brewing, glove-making, and other industries. Pop. (1871) 2976.

Witt. See DE WITT.

Witt'ekind, or **Wid'ukind**, the leader of the Saxons in their struggle with Karl the Great, came of a noble Westphalian house, and first appears at the head of the Saxon expedition against the Westphalian fortress of Eresburg (774). The emperor's return from conquering the Lombards drove him across the Weser, and after vainly renewing the revolt in 776, he fled to Denmark, but returning during Karl's absence in Spain, laid waste the Rhineland and surprised and annihilated the Frankish army on the Süntelgebirge (782). Karl retaliated by executing 4500 Saxon prisoners, an action that roused the entire Saxon race to arms. The battle of Detmold was drawn (783), but that of Osnabrück crushed W.'s hopes and forced him to enter upon negotiations, whose issue was that in 785 he accepted baptism in the imperial camp at Attigny, in Champagne. Karl, it is said, made him Duke of the Saxons and lord of Engern, and from his castle of Babilonie, near Lübeck, he exercised a mild and righteous sway till 807, when he fell in battle with Gerold, the Swabian duke. Various princely houses, as those of Brunswick and Sardinia, claim W. for the founder of their line. See Diekamp, *Widukind der Sachsenführer* (Münst. 1877).

Witt'enberg (the 'wood fortress'), a town of Prussia, province of Sachsen, on the right bank of the Elbe, 240 feet above the sea, and 42 miles N.E. of Halle by rail. The Elbe is here crossed by a stone bridge (1847) on eleven pillars and 903 feet long, and by a railway bridge of twelve arches and 964 feet long. There are three suburbs, all built since 1817. The Schloss, till 1542 the residence of the Saxon Electors, formed afterwards the citadel of W., which till 1873, when its fortifications were demolished, was a third-rate fortress. In the Schlosskirche (1490-99, and twice rebuilt after 1760, and in 1818), on whose doors Luther nailed his ninety-five theses (31st October 1517), are the tombs of Friedrich the Wise, Johann the Steadfast, Luther, and Melanchthon, as also portraits of the last two by Lucas Cranach, who was burgomaster of W. The doors were in 1858 replaced by bronze gates, on which the text of the theses is inscribed. The Stadtkirche has a famous altarpiece by Cranach, several of whose pictures decorate the Rathhaus. In the market-place is the colossal bronze statue of Luther by Schadow (1822), and near it is the statue of Melanchthon by Drake (1866). An oak-tree outside the Elsterthor marks the spot where Luther burned the papal bull of excommunication, 10th December 1520. The University of W. (founded in 1502), where Luther was professor of theology, was united to that of Halle, 12th April 1817. Its building is converted into a barrack. The theological college of W. occupies the 'Lutherhaus,' the Augustinian monastery where Luther was a monk. W. manufactures mats, linens, and woollens, and carries on brewing, distilling, and fishing. Pop. (1875) with the garrison (three battalions of infantry and artillery) 12,427. W., first mentioned in 1180, became under Albrecht I. the residence of the Dukes of Sachsen, and continued to be that of the Sachsen-W. line till the battle of Mühlberg in 1547, shortly after which it passed to the German Emperor. In the Seven Years' War W. was occupied by the Prussians, but was forced to capitulate to the Austrians, October 14, 1760. Seized by the French in 1806, it was taken by Tauenzein, 13th January 1814. See Schadow, W.'s *Denkmäler* (Wittenb. 1825); Meyner, *Geschichte der Stadt W.* (Dessau 1845); K. Schmidt, *W. unter Kurfürst Friedrich dem Weisen* (Erlangen 1877).

Witt'enberge, a town of Prussia, province of Brandenburg, at the confluence of the Stepnitz with the Elbe (here crossed by a railway bridge on 35 pillars, and 1367 yards long), 88 miles N.W. of Berlin by rail. It has a new Evangelical church in Gothic style, manufactures of machinery, railway-carriages, oil, soap, shoddy, and tiles, and a harbour with considerable shipping. Pop. (1875) 7640.

Woad (Old Eng. *wād*) is the *Isatis tinctoria* of botanists, a biennial herb of the natural order *Cruciferæ*. It grows 1-3 feet high, is of a glaucous hue, has long-stalked oblong-obovate radical leaves, sessile stem leaves 3-5 inches long, bears crowded panicles of yellow flowers, and pendulous one-celled indehiscent short pods. The plant occurs through the Mediterranean region, in Persia, and apparently in Japan. In Britain it is probably an alien, though it is stated that the ancient Britons stained their bodies with its juice. W. was at one time much cultivated for dyeing purposes, the blue pigment being obtained by fermentation of the pulped leaves. In its present use it is always mixed with indigo, and for the required supply is still grown in parts of Europe, and in Lincolnshire in England. The genus *Isatis* contains about 30 species, mostly natives of the Orient.

Wo'burn, a town of Massachusetts, U.S., 10 miles N.W. of Boston by rail. It has 11 churches, 36 schools, 2 weekly papers, and a library. Tanning, the principal industry, has flourished here since 1673. There are also an iron-foundry, chemical works, a glue-factory, &c. The water-supply is excellent. Pop. (1875) 8560. W. is one of the oldest towns of New England, having been founded in 1640.

Wo'den. See ODIN.

Wod'row, Robert, a Scottish minister and historian, son of James W., professor of divinity in Glasgow University, was born in 1679, studied at Glasgow, and in 1703 was licensed to preach by the presbytery of Paisley. A few months later he was appointed to the parish of Eastwood near Glasgow, where he spent the remainder of his days. He died 21st March 1734.

W.'s youth was nourished on the romantic tales of Covenanting heroism during the period of persecution, and when he grew up he resolved to devote his life to recording the labours and sufferings of the National Kirk. For this purpose he opened up a correspondence with the survivors of the persecution in all parts of Scotland. The result was the publication of *The History of the Sufferings of the Church of Scotland from the Restoration to the Revolution* (2 vols. 1721). He next wrote a series of Scotch ecclesiastical biographies, the MSS. of which form fourteen folio volumes, and are preserved in the library of Glasgow University. Of these the Rev. Dr. Leishman edited for the Maitland Club *Lives of the Reformers and most Eminent Ministers of the Church of Scotland* (3 vols. Glasg. 1834–45). A singularly curious and interesting work of W.'s entitled *Analecta, or Materials for a History of Remarkable Providences, mostly relating to Scotch Ministers and Christians* (4 vols. 1842–43), was also edited for the same club by Dr. Leishman. It throws a strange light on the intellectual and moral limitations—the ignorance, superstition, and credulity of Presbyterian divines in the time of W. In 1841 a 'W. Society' formed at Edinburgh for the publication of the early writers of the Reformed Church of Scotland issued as its first work *W.'s Correspondence* (3 vols. 1842–43) under the editorship of the Rev. Thomas M'Crie.

Woj'woda (Slav. *woi*, 'warrior,' and *wodit*, 'to lead'), from being a title among Slavonic races of generals chosen in sudden emergencies, came to be borne for life by the elective princes of Poland (q. v.), Moldavia, and Wallachia, in the last two countries being superseded by Hospodar (q. v.) in 1716. See also BANAT.

Wo'kingham, a market-town of Berkshire, standing within the bounds of Windsor Forest, 7 miles E.S.E. of Reading by rail, has a parish church (rebuilt 1864), a Gothic town-hall (1860), and the endowed elementary Palmer schools (1875) for 325 children. Pop. (1871) 2868.

Wol'cot, Dr. John, better known by his *nom de plume* of 'Peter Pindar,' was born at Dodbrooke, Devonshire, in May 1738, studied medicine in London, and after some time spent in Jamaica, established himself as a physician at Truro in Cornwall. Here he discovered the genius of Opie, 'the Cornish boy in tin mines bred,' and accompanied him to London, where he spent the rest of his life in cultivating the arts of satire and ridicule, in which he reached a rare proficiency. In 1785 he published no fewer than 23 'odes,' and in 1786 his *Lousiad, a Heroi-Comic Poem*, made sport of Majesty itself. The discovery of a 'louse among a dish of green pease set before George III., resulted in a penal decree that all the servants in the royal kitchen were to have their heads shaved!' The impudent familiarity of his low humour, and the chuckling jocosity of his vulgar fancy, here found a theme at once appropriate and inimitable. W. eagerly availed himself of the opportunity, and befooled his sovereign to his heart's content. Between 1778 and 1808 he published upwards of 60 satirical pamphlets—many little better than scurrilous (though not indecent) lampoons. Poor George III. is repeatedly assailed, and in general with success. The *Peeps at St. James's*, *Royal Visits*, *Lyric Odes*, &c., were once amusing reading. Even yet, one can laugh a little at 'The Apple Dumplings and a King.' W., however, was not merely a *farceur*. He could occasionally pen a tender ballad or song. Burns with reason thought well of his 'Lord Gregory,' paying the author the sincere homage of imitation. W. died January 13, 1819, and was buried in the churchyard of St. Paul's, beside Butler. A collection of his works in 4 vols. was published in 1796; the latest, in 5 vols., 1816.

Wolf, the name applied to a species of *Carnivorous* animal belonging to the family *Canidæ* or that of the Dog (q. v.), and nearly allied to both the dog and the fox. Like the former, it has a rounded pupil, while the tail is of moderate length and is not markedly developed. The fox, on the other hand, has a linear pupil and a bushy tail. The dog interbreeds with both the W. and jackal; and some naturalists maintain that the W. is the progenitor of some of the existing races of dogs. The muzzle of the W., as in the dog, is pointed, and the tongue smooth, the claws being non-retractile. The fore-feet have five toes, and the hind feet four. The molar teeth usually number 12 above and 14 beneath. The common W. (*Canis lupus*) is widely distributed over the European continent in its northern parts, and also in northern Asia. It extends to the north of Africa and India. Within comparatively recent times the W. was plentiful in Britain. In pre-Norman times, January was known to the English as 'wolf-month.' The W. would, however, seem to have become extinct in England about the close of the 15th c. In Scotland the last W. is said to have been slain by Sir Ewen Cameron of Lochiel in 1680; while in Ireland the animal was hunted so recently as 1710. But in the forests of Russia and north-eastern Prussia, the fastnesses of the Alps, the Pyrenees, the Apennines, and the former Turkish peninsula, it is still abundant. The Common W. is an animal of powerful build and morose determined aspect, attaining a length when full grown of fully 4 feet. The fur is of a well-marked grey colour, frequently tinted with fawn, and interspersed with black hairs, and giving to the fur of the spine especially a darkish tint. The under parts are white. The tail is not bushy, but is well developed. The ears are short and erect. In winter wolves congregate in immense packs, which pursue other living beings with a steady and relentless chase. They devour their sickly or wounded companions, and when pursued the best expedient of the hunters is to shoot several members of the pack, the majority halting to devour their fallen companions. Russian villages have numberless stories—many of them tragic and even horrible in the highest degree—of the successful ferocity of these famine-maddened monsters. Even in Spain and Italy their attacks are still dreaded. In summer, and when less hardly pressed by the want of food, the W. is suspicious and cowardly, and is readily scared by dogs or even by the semblance of pursuit. The Russian Government is of course the chief power in Europe which concerns itself with the capture and destruction of these animals, and returns submitted to the Imperial Government show that the amount of injury they inflict upon live stock is very great. Variations in colour and size have given origin to the idea of the distinct and specific nature of the various breeds or kinds of W. The Black W. (*Canis occidentalis*) of N. America probably has the best title to be regarded as essentially a distinct species, the Grey W. of America is regarded by many authorities as merely a variety. A doubtful species called the Dusky W. (*C. nubilus*) inhabits the N.W. States of America, and the White W. seems merely an albino variety of the black or grey species. The Prairie W. (*C. latrans*), a well-marked American species, is named from its habitat. It is a dreaded enemy of buffaloes and deer. The Coyote (*C. schropus*) or Cajote is a species of W., resembling the fox in shape, and also inhabiting the prairie-lands of the New World. The young of wolves number from three or four to eight or nine, and the male W. is assiduous in his attentions to his mate and family. The young are usually born in March.

Wolf, Christian Freiherr von, an eminent German philosopher, was born at Breslau 24th January 1679. He studied at Jena and Leipzig, and was appointed in 1709 professor of mathematics and natural history at Halle. His teaching and writings here gave such offence to the pietist party that they raised an outcry against him, which induced the government to deprive him of his chair and oblige him, under penalty of the halter, to quit Halle in twenty-four hours and Prussian territory in two days (1723). The storm finally turned to W.'s advantage. A commission was appointed after a considerable interval to examine the case, and the result of their investigation was that the outcast was called back to Halle by Friedrich II., and appointed Professor of the Law of Nature and Nations, with the titles of Privy Councillor and Vice-Chancellor. In 1743 he became Chancellor, and was raised to the rank of a baron of the empire by the Elector of Bavaria. He died 9th April 1754. W.'s merits as a philosopher are thus stated by his German critics. 'He claimed again, in the name of philosophy, the entire field of knowledge, he made philosophical method as such an object of attention, he made German the modern language of philosophy.' To this it may be added that his principal conceptions were borrowed from Leibnitz. He divided his system into metaphysics and practical philosophy. Logic he considered as an introductory study. Metaphysics he subdivided into ontology, cosmology, psychology, and natural theology; and Practical Philosophy into ethics, economics, and politics. He discussed these subjects under a mathematical method, and without saying anything very original about them.

W.'s system, once widely popular, vanished as soon as Kant was understood. See Ludovici's *Ausführlicher Entwurf einer vollständigen Historie der Wolf'schen Philosophie* (3 vols. Leip. 1737); Baumeister's *Vita, Fata et Scripta* (1739); and *C. W.'s Eigene Lebensbeschreibung*, edited by Wuttke (Leip. 1841).

Wolf, Friedrich August, an illustrious classical scholar and critic, was born 15th February 1759 at Haynrode, near Nordhausen. Before leaving the gymnasium of Nordhausen, he had not only read the chief ancient authors, but had acquired an extensive knowledge of the languages and literatures of France, England, Italy, and Spain. In 1777 he entered the University of Göttingen, but was an irregular attendant at professors' lectures, giving himself chiefly up to intense and solitary study. As a consequence he was hardly known, and where known not particularly liked. In 1782 he was appointed rector of the *Bürgerschule* at Osterode in the Harz, and next year he was called to Halle as professor of philosophy and paideutics. Here he laboured upwards of twenty years with the highest enthusiasm for the cause of education. His ambition was to produce a great race of teachers, who should be instinct with the noblest and purest spirit of antiquity. In 1793 appeared his great work, *Prolegomena in Homerum* (3d and 4th editions by J. Vekker, with additions from W.'s papers, Berl. 1872 and 1875). In this he affirmed that the two great Grecian epics were not the work of one man, but of a number of Homeric rhapsodists, and he set himself with all his vast resources of learning and genius to prove his thesis. This 'epoch-making' work created a profound sensation, and though it may be too much to say that he absolutely succeeded in proving his contention, yet it has had the effect of profoundly and permanently modifying the opinions of Homeric scholars on the manner of the composition of the *Iliad* and *Odyssey*. From a literary point of view his labour has been of immense service. He for ever dispelled that exaggerated and unmeaning worship of 'Homer,' which, combined with an utter want of appreciation of the real merits and beauty of the Homeric poems, was so ridiculous a feature of the old classical scholarship. The University of Halle was suppressed in 1807, and W., who had repeatedly declined calls to other universities, then removed to Berlin, where he entered the ministry of Public Instruction, but soon resigned his office that he might give himself unreservedly to work of academic teaching, which was the most sacred passion of his life. In 1824 he went south, on a voyage for the sake of his health, but died 8th August of that year at Marseille. During a long lifetime devoted to classics, W. published a large number of works. Of these may be mentioned his editions of Homer (4 vols. Leip. 1794-95), many orations of Cicero, dialogues of Plato, and plays of Aristophanes, besides various works on classical antiquities. A most important and characteristic work, *Ideen über Erziehung, Schule und Universität*, was posthumously published by his son-in-law, Körte, in 1835. See Körte, *Leben und Studien F. A. W.* (2 vols. Essen 1833); Gottholdt, *Fr. Aug. W. die Philologen und die Gymnasien* (Konigs. 1843); Arnoldt, *W. in seinem Verhältnisse zum Schulwesen und zur Pädagogik* (2 vols. Braunschw. 1861-62); and Volkmann, *Geschichte und Kritik der Wolf'schen Prolegomena zu Homer* (Leip. 1874).

Wolf Hound, a species of dog used in hunting the wolf. Allied in some respects to the shepherd's dog, it is chiefly found in Norway and Sweden, but has been introduced into other European countries. The name is also given to a species of black dog bred by the Indians of Florida, which, according to Bartram, 'differs in nothing from the wolves of that country except in barking.'

Wolfe, James, an English general, son of Lieutenant-General Edward Wolfe, was born at Westerham, Kent, 2d January 1727. He was educated at Greenwich, and entered the army at an early age, becoming second-lieutenant at fifteen. He was present at the battles of Dettingen, Fontenoy, Falkirk, and Culloden, and was wounded at Lawfeldt (1747). He afterwards commanded a regiment in Scotland, and succeeded in maintaining the strictest discipline among his men, while at the same time he secured their affections in an unusual degree. W. took part in the expedition against Rochefort (1757), was made a brigadier-general in the following year, and greatly distinguished himself in the capture of Louisburg, Cape Breton, under the command of General Amherst. On his return to England Pitt determined to trust him with the command of the expedition he was planning against the French possessions in Canada. His fleet was a strong one, but was unable, owing to the draught of the vessels, to co-operate with him against Quebec. The land forces, on the other hand, amounted to rather less than 8000 men, and with these he had to attack a town whose situation rendered it almost impregnable, defended by a large French force under an intrepid and able leader, Montcalm. On the 8th of June 1759 he landed on the Ile d'Orleans, whence he commenced an ineffectual bombardment of the town. He next attacked the French works at the mouth of the Montmorency (31st July), but was repulsed with considerable loss. At last the advance of the season and the reduction of his troops by sickness, &c., forced him to make a decisive effort. On the night of the 12th September he took 3600 men in boats to a point about two miles above Quebec. Before morning they had scaled the Heights of Abraham, which commanded the city. Montcalm left his trenches to dislodge them from this position, and a fierce conflict resulted in the total defeat of the French. Unhappily both generals were mortally wounded. W. died in the moment of victory, saying, 'God be praised! I die happy.' His adversary lived until next day. Four days afterwards Quebec fell, and the final blow was struck at the French power in Canada. W. was buried in the parish church of Greenwich, and the House of Commons voted him a monument in Westminster Abbey. He was a man of singularly pure and lofty character, and would probably, had he lived, have been a great general. See Wright's *Life of Major-General James W., founded on Original Documents and Illustrated by his Correspondence* (Lond. 1864); also Thackeray's *Virginians*.

Wolfe, Rev. Charles, born at Dublin, 14th December 1791, was educated at Winchester and Dublin University, where he graduated B.A. in 1814. His verses on the *Burial of Sir John Moore* were written in 1817, and soon after found their way anonymously into the newspapers. No poem perhaps ever thrilled a nation more instantaneously; and it falls upon the ear to-day as freshly and powerfully as it did sixty years ago. It is the perfection of true-hearted pathos: an incident at once romantic and sublime is recorded with a patriot's pride and a soldier's emotion. Having taken orders, W. became successively curate of Ballyclog in Tyrone and rector of Donoughmore. Consumption, unhappily, soon showed itself in his system, and after some unavailing attempts to fight the enemy by visits to the S. of England and France he died at the Cove of Cork, 21st February 1823. His *Remains*, chiefly sermons and poems, were first published in 1825 by the Rev. John A. Russell, Archdeacon of Clogher.

Wolf'enbüttel, a town of Brunswick, Germany, on the Ocker, 13 miles S. of Brunswick by rail. It is an old town with 4 churches, the largest of which is that of St. Mary, and a ducal palace, part of which is now converted into a theatre, and part used as a manufactory of tapestry. Opposite this is the Pantheon, built on the model of that at Rome in 1723, and containing in its upper story the famous W. library, with 300,000 volumes, including more than 10,000 MSS., 800 Bibles, Luther's Bible with autograph notes, and other relics of the Reformers. According to the *Academy*, January 11, 1879, the state of this library is disgraceful, with walls and ceilings falling in, and the valuable collection perishing from damp and decay. W. manufactures leather and yarn, and has also iron-foundries, copper-smelting works, &c. There is a trade in corn and vegetables. Pop. (1875) 11,105. The town, which is very ancient, was the residence of the dukes of Brunswick-W. until 1754.

Wolf'enbüttel Frag'ments. See Lessing and Reimarus.

Wolff'ian Bod'ies, or **Primor'dial Kid'neys**, are two organs developed in *Vertebrate* animals. In man they appear at about the third week of intra-uterine life, and are situated one on each side of the primitive spine. Above, each Wolffian body ends blindly, and opens below into the bladder. In structure the Wolffian body resembles the Kidney (q. v.). It has an excretory canal resembling the Ureter (q. v.), and exhibits a glandular and tubular structure comprising Malpighian tufts and bodies. The W. B. are attached to the *diaphragm* by a *superior ligament*, and to the spine by an *inferior ligament*. The W. B. secrete urine from the blood of the fœtus, but they are partly absorbed in the formation of the true and permanent kidneys, and partly assist in the formation of the genital organs. The *ducts* of the W. B.

in the male ultimately become the *vas deferens* and *ejaculatory duct*; but in the female, the Wolffian ducts entirely disappear. It is worthy of note that in fishes and amphibians the W. B. remain permanently as the kidneys of adult life.

Wolf Fish (*Anarrichas lupus*), also named Sea Cat and Swine Fish, is a *Teleostean* fish, allied to the Blenny (q. v.), and deriving its name from a peculiar development of the teeth, which consist of front incisors, above shelved, interlocking in an exact manner, three rows of palatal grinding teeth, and two rows of similar teeth in the lower jaw. The W. F. may attain a length of 4 or 5 feet. The dorsal and anal fins are long and single, and the tail fin is unforked. The colour is an olive-green above, marbled with brown on the head especially. The fish feeds on molluscs and crustaceans. Dr. A. Wilson, describing his dissection of a W. F. (*Nature*, April 1879), mentions that the stomach contained starfishes, shells, gravel, and crustaceans. The skin is glutinous. The W. F. is said to be fierce, and to attack its captors. The flesh tastes like that of cod. An allied species (*A. vomerinus*) is found off the American coasts.

Wolf'ram von Esch'enbach. See ESCHENBACH.

Wolf's Bane. See ACONITE.

Wolf Spider, a name given to spiders of the genus *Lycosa*, in which the body is large and hairy, and in which the fourth pair of feet is larger than the other pairs. It makes no web, but roams about in search of prey, and hides beneath stones. *L. Tarantula* is the Tarantula (q. v.) of Italy.

Wol'gast, a town of Prussia, province of Pommern, on the left bank of the Peene, 4½ miles from its influx into the Baltic, and 40 miles S.E. of Stralsund by rail. Its harbour is shallow, and larger vessels load and unload on the Ruden, an island at the river mouth. W. has the remains of an old castle, the ancestral seat of the Dukes of Pommern. Its industries are weaving, boat-building, and the manufacture of leather and tobacco. It has also an active trade in ships' stores. Pop. (1875) 7269. W., which was strongly fortified early in the 12th c., was destroyed in 1628 by Wallenstein, in 1630 by the Swedes, in 1637 by the Imperialists, and in 1638 again by the Swedes. In 1675 it was taken by the Great Elector, was plundered by the Russians in 1713, and by the Swedes again in 1715. But small remains now exist of its former fortifications.

Woll'aston, William Hyde, M.D., F.R.S., was born in Charterhouse Square, London, August 6, 1766. He entered Caius College, Cambridge, where he took the degree of M.D. in 1793. The same year he was elected a fellow of the Royal Society, of which he was chosen one of the secretaries in 1806. Though he settled in London with the intention of entering into practice as a physician, he soon decided to devote himself wholly to the pursuit of science, and in the departments chiefly of chemistry and optics he has earned a lasting reputation. Not content to discover new truths, he strove to direct these to practical ends; and from many of his applications, notably the method of manufacturing platinum, he amassed a considerable fortune. His first contribution to the *Philosophical Transactions* is an essay on *Gouty and Urinary Concretions* (1797), in which he records the discovery of some new chemical compounds, phosphate of lime, oxalate of lime, and ammonia-magnesium phosphate. In 1804 and 1805 he discovered palladium and rhodium, and in 1809 identified the supposed new metal tantalum with columbium previously discovered by Hatchett. He proved the identity of frictional and voltaic electricity, and made many valuable researches into the phenomena attending the action of the cell. In optics he is best known as the inventor of the camera lucida, the goniometer for measuring angles of crystals, and the cryophorus for freezing water by its own evaporation; and in the *Philosophical Transactions* for 1803 there is published a valuable paper *On the Oblique Refraction of Iceland Crystal.* His 'Bakerian Lecture,' *On a Method of Rendering Platina Malleable*, is published in the *Philosophical Transactions* for 1829. W. died December 28, 1828.

Wolse'ley, Sir Garnet Joseph, the eldest son of Major W., a cadet of an ancient Staffordshire family, was born June 4, 1833, at Golden Bridge House, county Dublin. He entered the army in 1852 as ensign in the 80th regiment, but the greater part of his regimental service was with the 90th foot. W. first smelt powder in the second Burmese war of 1853, when he was severely wounded in leading a storming party. After Inkerman he went to the Crimea, and was again dangerously wounded in a hand-to-hand fight in the trenches. He next served through the entire Sepoy War of 1857-58, during the later portion on the staff of Sir Hope Grant. At the second relief of Lucknow he was one of the first to enter the Residency. In 1860, now a brevet-colonel, he accompanied Sir Hope Grant to China as head of the topographical department, and witnessed the capture of the Taku forts and the plunder of the Summer Palace at Pekin. After a holiday in England of only a few months, he embarked for Canada in 1861, on the alarm of the *Trent* affair, and here he remained almost continuously until 1871, first obtaining an independent command as chief of the Red River Expedition in 1870. The unqualified success of that arduous expedition gained for him the honour of knighthood and the appointment of Assistant Adjutant-General in the Horse-Guards. In the autumn of 1873 he was appointed to the supreme military and civil command on the Gold Coast, and in a few short months broke the power of the Ashantees, and burnt their capital of Coomassie. As compared with earlier and later savage wars, it may be said that none was ever so successful and so cheap as this. On his return he was rewarded with a grant from Parliament of £25,000, and the rank of Major-General. In 1875 he was sent to Natal as temporary governor, to set in order the disturbed affairs of the colony, in 1878 to Cyprus as High Commissioner and Commander-in-Chief, and in May 1879 to South Africa as Governor of Natal and the Transvaal, and invested with supreme civil and military authority in the territories disturbed by the Zulu war. Sir Garnet W. is the typical representative of the modern officer, who combines intellectual training with professional zeal. His *Soldier's Pocket-Book for Field Service* (1st ed. 1869; 3d ed. 1875) is the model treatise of scientific warfare applied to practical details. He has published various other papers of military subjects. See C. R. Low's *Memoir of Sir Garnet J. W.* (2 vols. Lond. 1878).

Wol'sey, Thomas, son of a well-to-do Ipswich townsman, was born in March 1471, and from the free school of his birthplace went up to Magdalen College, Oxford, where, graduating in his sixteenth year, he gained the nickname of 'Boy Bachelor.' To a college fellowship was joined the mastership of Magdalen School, and from the Marquis of Dorset, father of three of his pupils, he received the living of Limington, Somersetshire, in 1500. His second patron was Archbishop Deane, his third Sir John Nafaut, Treasurer of Calais; and by the latter, whom he served as deputy, he was brought to the notice of Henry VII. His great abilities, coupled with dexterous addresses to Fox and Lovel, the reigning favourites, raised W. high in Henry's favour; and, sent on an embassy to Flanders, he added to skilful conduct such singular despatch that the king chid him for not having started yet, when in fact he appeared to notify his return—a feat rewarded with the deanery of Lincoln (1508). His negotiations for Henry VII.'s marriage to Maximilian's daughter, Margaret of Savoy, were frustrated by Henry's death (1509); but with W. a change of masters meant always a rise to fresh advancement. Fox, casting about for a rival to Surrey's influence, made him king's almoner, and for reward was himself supplanted by W., who by debonair ministering to royal pleasures and subtle flattery of royal vanity soon 'took,' says Cavendish, 'the length of young Harry's foot, and fitted it with an easy shoe.' All state business was now disposed by W., and most church preferments were bestowed on him—the rectory of Torrington (1510), a Windsor canonry (1511), a prebend of York (1512), its deanery and the French bishopric of Tournay (1513), the see of Lincoln and the archbishopric of York (1514), to which were added the temporalities of other wealthy dioceses and enormous pensions from various foreign powers. In 1515 he was made a cardinal, and succeeded Warham as lord chancellor; in 1519, after three years' delay, Henry procured him the legatine authority, which formed the keystone of his proud position. His policy from the first was one of peace, a peace in which absolutism grew side by side with the New Leaving and outward prosperity, whilst king and minister cherished each his own ambition, Henry of the imperial and W. of the papal crown. The balanced contest between France and Spain lasted ten years (1513-22), and though the Spanish cause was popular as ever with the English nobles, no man durst wag his head in discontent, lest it fell off with Buckingham's. But Henry, still nursing hopes of winning

back his 'French inheritance,' and ascribing to François I. his failure to seat himself upon Maximilian's throne (1519), was bent on a second war with France, and W. must needs submit,—Karl V., to make sure of him, engaging to secure his election to the see of Rome. Twice it fell vacant (1522-23), and twice was the cardinal duped, whilst at home his attempts to meet the expenses of useless French campaigns by arbitrary taxation and benevolences resulted in defeat. Pavia gave everything to Karl, to Henry nothing; and in the flush of his master's disappointment W. was able not only to renew the French alliance, but to exact as its price £285,000. Revenge and ambition, each prompting a final rupture with the Emperor, might both be gratified by divorcing the heirless Catherine and marrying Henry to a French princess. Catherine was the Emperor's kinswoman, and the head of the Spanish party, and Henry had grown estranged from her since 1524; but a wife to his liking could only be had through a pope of his own choosing, and W. designed that choice should fall upon himself. The scheme's success made it essential jealously to uphold the papal prerogative, and at the same time hinder the reigning Pope from delivering sentence, so that Henry and François, weary of delays, might end by making W. antipope. This object he so steadily pursued, even after a passion for Anne Boleyn had superseded Henry's conscientious scruples (1527), that he rejected Karl's stupendous bribe not to accept the patriarchate of Gaul. But Henry's desires, outstripping W.'s policy, brought matters to an untimely crisis; and when, after four years spent in vacillating negotiations, Karl by the mouth of Clement VII. cited the case to Rome (1529), the cardinal knew that his doom was sealed, if only by the Boleyns' enmity. Charged with transgression of the Statute of Præmunire, he temporarily staved off ruin by sacrificing dignities and that vast wealth whose noblest use had been the foundation of the colleges of Christ Church (q. v.) and Ipswich. Part of it was restored to him, and he was suffered to retire to his archbishopric; but only to be re-arrested in the midst of preparations for a magnificent installation, and brought towards London. Dysentery attacked him on the way, and at the Abbey of Leicester he breathed his last, 29th November 1530. As founder of an overwhelming despotism, as a bitter religious persecutor, and as a priest of immoral life, the low-born cardinal deserves more wonder and censure than pity and admiration. His influence on English history was great, since 'his long tenure of the whole papal and civil authority within the realm led men at a later time to acquiesce in Henry's own supremacy.' See the Lives of him by Cavendish (ed. by Holmes, Lond. 1852), Fiddes (Lond. 1724), Galt (Lond. 1812), and Martin (Lond. 1862); also Froude's *History of England* (vols. i.-ii. 1856); Brewer's *Letters and Papers of the Reign of Henry VIII.* (4 vols. Lond. 1862-75); and Lord Acton's *W. and the Divorce* in the *Quarterly Review* (January 1877).

Wolverhamp'ton, a town of S. Staffordshire, England, 12¾ miles N.W. of Birmingham by rail, stands upon rising ground amid a network of railways and canals. Of its numerous churches the finest and most ancient is the cruciform St. Peter's, which, dating from the 14th c., was enlarged and elaborately restored (1859-65). Later edifices are St. Philip's (1859), St. Luke's (1861), St. Andrew's (1866), and St. Jude's (1868), all in First Pointed style, as also are E. Pugin's Catholic church (1867) and a Wesleyan chapel (1863), with a spire 115 feet high. The public buildings include a town-hall (1868), corn-exchange (1852), market-hall (1853), agricultural hall (1863), theatre (1856), free library (in connection with which a Naturalists' and Archæological Department was formed in 1876), an Athenæum, concert-hall, &c.; and there are also an orphanage for 200 children (1868), the S. Staffordshire Hospital, and a free grammar-school (founded 1515; rebuilt 1874). In the triangular open space in the centre of the town, formerly and still partially used as a market-place, the Queen unveiled (1866) a bronze equestrian statue of the Prince Consort; and in June 1879 Earl Granville unveiled in front of the Agricultural Hall a statue of the Right Hon. C. P. Villiers, the senior borough member. Lock-making has for now two centuries been W.'s staple industry, next to it rank tinplate-working, japanning, and galvanising, and there are besides large iron and brass works, smelting furnaces, chemical, coal, grease, colour, and varnish works, and in the neighbourhood collieries, ironstone mines, and quarries. W. publishes one daily and three weekly newspapers, and its parliamentary borough (with a pop. in 1871 of 156,078) returns two members to Parliament. Pop. (1801) 12,556, (1879) 75,100.

Wol'verine. See GLUTTON.

Womb, or **U'terus,** the organ in which the young of *Mammalia* (q. v.) are developed and protected, and from which at birth they are expelled. It essentially consists of the united *oviducts* or *Fallopian tubes*—the ducts leading from the *ovaries* (see OVARY) to the external surface of the body. Thus in birds and in the lowest quadrupeds or *Monotremata* (q. v.) the oviducts simply open into a *cloaca* or chamber common to the efferent ducts of the urinary and digestive systems, without uniting to form a W. In the kangaroos and other *Marsupialia* (q. v.) there is a similar condition of the W., but in the latter animals the two oviducts open into two vaginal tubes, and these in turn open into a *urogenital canal*, which, however, is distinct from the *rectum*. In higher or *placental* Mammalia the oviducts coalesce to form a true *uterus* or W., which may, however, exhibit, as in the horse, traces of its double nature in the presence of two *cornua* or 'horns' at its fundus or base. In the pig these cornua are extremely elongated, but in Rodents, such as the rabbit, the organ is truly double. The uterus or W. is thus to be viewed as a special development of the oviducts, and the impregnated ova from the ovaries, passing down the oviducts, rest in the W. and there undergo development. The W. communicates externally by the *Vagina* (q. v.), through which the child is expelled at birth.

The W. of the human subject is, in the virgin or unimpregnated state, a pear-shaped organ, slightly flattened from before backwards. It lies in the *pelvis*, between the bladder above and the rectum or last portion of the bowel beneath. The fundus upper end or base is directed upwards and forwards, its lower extremity downwards and backwards. The average length of the W. is 3 inches, its breadth 2 inches, and its thickness about 1 inch. The average weight is about 1½ ounces. The body of the W. gradually narrows from above downwards until it opens into the vagina by a neck or *cervix*, at the extremity of which is the *os uteri* or mouth of the W. This aperture is transverse and is bounded by two lips, of which the anterior is thick, and the posterior long and narrow. The W. is kept in its place by means of *six ligaments*. These are (1) the *Vesico-uterine* or *anterior ligaments* attaching the organ to the posterior surface of the bladder; (2) the *recto-uterine* or *posterior ligaments* attaching the W. to the rectum; and (3) the two *broad* or *lateral ligaments* by means of which the W. is attached to the walls of the pelvis. On dissection the W. is found to present a small internal cavity, its walls being proportionally very thick. The cavity of the *cervix* or neck has a corrugated appearance named the *arbor vitæ*. The oviducts or Fallopian tubes open into the organ at its base by two minute apertures. The W. consists of three coats or layers. The external coat is of *serous* nature. The middle coat is *muscular*, and is composed of unstriped fibres dispersed in layers, this coat undergoing a great thickening during pregnancy. The inner or *mucous* coat is thin and smooth, and is closely adherent to the middle coat. This inner coat is of reddish colour, and is lined by ciliated *epithelium*, whilst it is provided with numerous mucous follicles and glands. During menstruation, the lining membrane of the W. undergoes important changes, and appears to be renewed after each menstrual period. The W. derives its *uterine arteries* from the internal iliac trunks, the *ovarian arteries* of the W. coming from the *abdominal aorta*. The arteries of the W. have a very tortuous course, and the veins are large, constituting in the pregnant uterus the *uterine sinuses*. The nerves of the W. are derived from the *inferior hypogastric* and *spermatic plexuses*, and nervous filaments are also supplied to the W. from the third and fourth *sacral nerves*. In old age the W. becomes smaller, and the *internal os*, as well as the external *os uteri*, may be obliterated. During pregnancy the W. increases in weight from 2 to 3 lbs., and becomes enormously enlarged, extending upwards into the abdominal cavity.

Diseases of the W.—The W. is subject to a great variety of diseases, the more important of which are the following. (1.) *Endometritis*, or inflammation of the lining membrane of the W. It may be acute or chronic, and may affect the lining membrane of the cervix, or of the body alone, or it may be general and attack the whole mucous uterine tract. The most

frequent causes are cold from exposure during menstruation, suppression of menstruation, vaginitis, and constitutional diseases of septic or asthenic character, such as measles, scarlatina, &c. The symptoms are pain, weight and dragging in the pelvis, and pain in the back, groins, and thighs, vesical and rectal tenesmus, and, after a time, uterine tenesmus. After a few days there is a muco-purulent discharge which may induce vaginitis. Early treatment is of primary importance, and should consist in complete rest of body and mind. In severe cases the horizontal position should be rigidly maintained. Opium, or its preparations, should be given in full doses. A warm linseed poultice, covered with oiled silk, should be applied over the hypogastrium. The diet should consist of fluid food chiefly, as milk, beef-tea, &c. When the discharge begins to show itself, the vagina should be syringed with copious injections of warm water, or with demulcent infusions of linseed or starch, or infusion of poppies, and this treatment should be persevered in three or four times daily until recovery, or until the disease may have passed into the chronic form. The acute form of endometritis usually implicates the entire mucous membrane; but the chronic form may be limited to the cervix or the body. The lining membrane of the body of the W. is also liable to chronic inflammation, the affection being sometimes called *uterine catarrh*, *uterine leucorrhœa*, and *internal metritis*. The utricular follicles are the seat of the disorder, the uterine leucorrhœa being an exaggeration of their secretory functions. The chief symptoms are leucorrhœa; menstrual disorders; pain in the back, groins, and epigastrium; nervous disorders, as neuralgic headache and hysteria; tympanitis and sterility. In the treatment of such cases means should be adopted for sustaining and improving the general health of the patient. Iron, the mineral acids, quinine, bromide of potassium, or nux vomica may be administered.

(2.) *Areolar hyperplasia* of the W., or *chronic parenchymatous metritis*, is a disease of the W. of very frequent occurrence, and, as a general rule, is a consequence of subinvolution. When the affection involves the entire W., the more prominent symptoms are a dull, heavy, dragging pain through the pelvis, much increased by locomotion; a dull pain beginning several days before menstruation, and lasting during that process; also pain in the mammæ; pressure on the rectum and bladder, with tenesmus; nausea and vomiting, and great nervous disturbance. In such cases, general hygienic treatment is of the utmost importance; ferruginous and vegetable tonics should be administered; and, during the stage of enlargement, ergot, kept up for a considerable time, produces good results. The local or topical treatment is of a complicated nature, consisting in depletion, vaginal injections, the warm sitz-bath, the local application of alteratives, and the excision of a portion of the neck of the W., or its removal by means of the galvano-cautery. (3.) *Granular degeneration of the cervix* of the W. consists in a granular development on the smooth face of the cervix, just within the os, and is a concomitant of most of the diseased conditions of the parenchyma and lining membrane. Profuse leucorrhœa may be the only prominent symptom.

The foregoing diseases of the W. are very frequently complicated with *displacements* of the W., of which there are several varieties. (1.) *Descent* or *prolapsus* of the W., popularly known as *Falling of the Womb*, is of frequent occurrence, and may occur very suddenly and unexpectedly, or gradually and by successive steps. The most frequent predisposing causes are child-bearing, laborious occupations, advanced age, and habitual constipation. The exciting causes are (*a*) those increasing uterine weight; (*b*) those enfeebling uterine support; (*c*) those forcing the W. down by force applied above; and (*d*) those drawing it down by traction from below. The treatment consists in removing the cause in so far as it is removable, and in supporting the prolapsed W. by some mechanical contrivance, of which there are several, or by an appropriate surgical operation. (2.) *Anteversion* of the W. is an anterior inclination of the W. so that the fundus approximates the symphysis pubis, and the cervix retreats into the hollow of the sacrum. (3.) *Retroversion* of the W. is a posterior inclination of the W., so that the fundus approaches the sacrum and the cervix advances towards the symphysis pubis. (4.) *Flexions* of the W. are of frequent occurrence, and give rise to many distressing symptoms. (5.) *Antiflexion* is a bending of the organ, so that the fundus, the cervix, or both, are bent more or less sharply forwards. (6.) *Retroflexion* is the bending of the body of the W. towards the sacrum, so as to create an angle on the posterior wall. (7.) *Lateroflexion* is a bending of the W. to the right or left side as a consequence of disease of its proper tissue, or direct pressure. All these conditions of displacement and flexion may be mitigated by the mechanical support of specially adapted pessaries. (8.) *Inversion* of the W. is the turning of the W. inside out, and the inversion may be partial or complete. There are various methods of replacing the inverted W., but the affection is a very serious one; and, in some cases, it may be necessary to remove it by operation.

The W. may also be the seat of various tumours, the more important of which are the fibrous and the fibro-cystic. *Fibroid tumours* of the W. most frequently appear in the body or fundus, and they may develop singly or in considerable numbers, and attain a great size. The simple tumour, which is single, is generally spherical, and is connected by loose connective tissue with the W. The compound tumour is made up of a number of small fibroids, connected by loose connective tissue. These tumours are called submucous, when they lie under the mucous membrane; subserous, when under the peritoneum; and interstitial, when in the walls of the W. The treatment, in the great majority of cases of the interstitial and subserous variety, is merely palliative.

Cysto-fibromata, or *fibro-cystic tumours* of the W., are not of very frequent occurrence, and up to the year 1869 only fourteen cases had been recorded, two of which had been discovered by post-mortem examination. *Polypus* of the W. is a tumour covered by the mucous membrane of the W., attached by a pedicle or stem, and originating in a hypertrophy of some of its proper tissues, the muscular, the connective, or the glandular. The varieties of polypus are the cellular, the glandular, and the fibrous. The *cellular polypus* is a pear-shaped tumour, varying in size from a marble to a hen's egg. It consists of connective tissue in a state of hypertrophy, and is covered with mucous membrane. It is generally attached to one wall of the cervix, and sometimes the pedicle is very long and slender, so that it hangs outside the vulva. The *glandular polypus* consists in hypertrophy of the Nabothean glands, or of the utricular follicles, and arises more frequently from the cervix than from the body. The *fibrous polypus* is a submucous fibroid tumour which, being slowly extruded from the uterine parenchyma by its contraction, acquires a pedicle and the characteristic form of a polypus. They usually arise from the body of the W., but occasionally from the rim. The treatment may be either palliative or curative. The palliative treatment consists in keeping the W. in position by an appropriate pessary, keeping the patient in bed during the menstrual periods, and giving cannabis indica, gallic acid, or ergot. During the inter-menstrual periods, ergot should be given freely to favour extrusion of the polypus. The curative treatment consists in removing the polypus by either of the three following methods; excision, torsion, and traction; ecrasement, or the galvano-caustic wire.

Sarcoma, or Cancer of the W., is the most dreaded of all diseases. Of late years it has been described by German pathologists and surgeons as a disease distinct from cancer, though in many features closely resembling it. In sarcoma, the cells are merely exaggerated reproductions of those of the mother tissue; but in cancer the cells are heteroplastic to the mother tissue. The distinction, however, can only be made out by the microscope. Between cancer of the W. and the same affection in other parts of the system there are no marked differences. The most frequent form of cancer of the W. is the medullary, which is, both in its development and subsequent course, the most acute of all cancers, so that the prognosis is extremely unfavourable. Sir James Simpson gives an average duration of the disease of from 2 to 2½ years; Lebert, about 16 months; West, about 15 months; and Barker, about 3 years and 8 months. Death is usually due to hæmorrhage, or irritative fever of a typhoid form; or from some one of the numerous complications which accompany the disease.

The treatment of cancer of the W. is of a very unsatisfactory nature as regards cure, the disease and many of its complications being entirely beyond the resources of art. If detected early, and if the disease is confined to the cervix, the cervix should be removed by amputation. If the disease be scirrhus or encephaloid cancer, some relief may be afforded; but if it be epithelioma, a cure may be affected. The best mode of operating is by the

galvano-cautery, for by it the blood-vessels and the lymphatics are sealed up. The operation, although it may not permanently cure, prolongs life. If the diseased portion cannot be completely removed, it should be destroyed as far as possible by such means as strong acids, by potassa cum calce, by the gas-jet cautery, or by the galvano-caustic knife. Relief from pain may be afforded by the administration of opium by the mouth, the rectum, the vagina, or under the skin, or chloral hydrate may be given in scruple doses. The fœtor of the discharges may be corrected by the injection of solutions of carbolic acid, permanganate of potash, persulphate of iron or of the iodide of lead. There are no specifics for the cure of cancer, but tonic medicines may be given, and the strength should be supported by generous diet and fresh air, a residence in the country if possible, and the administration of stimulants. Abundance of milk and beef tea should be given, iron should be freely administered, and quinine will be found to be the most efficacious of tonics. See *A Practical Treatise on the Diseases of Women*, by T. Gaillard Thomas (Philad. 1878); and *A Handbook of Uterine Therapeutics and Diseases of Women*, by Edward J. Tilt (Lond. 1878).

Wom'bat (*Phascolomys fossor*), a species of *Marsupialia* (q. v.) found in Australia. Its food consists of roots and vegetable matters; the teeth have two incisors, two premolars, and eight molars in each jaw. Canine teeth are wanting. The incisors and molars grow from permanent pulps, a character in which the W. differs from all other marsupial mammalia. The animal has a stout body and short legs. The body is covered with a brown woolly fur, but the tail is extremely short. The average length is 3 feet. The W. lives in burrows, which it excavates by means of the strong digging-claws with which its forefeet are provided.

Women's Rights, the name applied, sometimes in derision, to the claims for the political and social enfranchisement of women put forward by a certain school of modern thinkers. It is to the influence of such women as Madame Roland and Madame de Staël, Mary Wollstonecraft and George Sand, that the movement in reality owes its origin, but it first took definite and practical shape in America, where an agitation was commenced in 1848, growing, strange to say, out of the anti-slavery agitation, with which it would seem at first sight to have little connection. 'Conventions' were held in different cities, and were largely attended, and for the most part conducted, by women. The political portion of the movement was headed by such women as Amelia Bloomer, Lucretia Mott, and Susan B. Anthony, while their followers earnestly strove to fight their way, not only to the franchise, but to higher education and the learned professions. Annual conventions were held in New York from 1852 to the outbreak of the war, and Women's Suffrage associations were established throughout the country. In 1869 the elective franchise and the right to sit on juries were granted to women in Wyoming Territory, and in the following year the franchise was granted in Utah. A female suffrage proposal passed the lower house of the Iowa legislature in 1876, and was barely thrown out in the Senate. In that State women have long held appointments as notaries, public school superintendents, &c., while in Illinois and one or two other States the legal profession is open to them. A 'Woman's Declaration of Independence' was presented to the President on the Centennial Independence day, 4th July 1876. There are ten or a dozen W. R. journals in America edited, and for the most part written, by women. In general journalism, too, women are very largely employed. Female doctors are very numerous, having gained their diplomas either at American colleges, of which five or six undertake the medical education of women, or on the Continent. In the other learned professions, the Church not excepted, prominent positions are occupied by women. There are in America numerous admirable institutions for the higher education of women; on the lecture-platform women are popular and successful; and since the time of the war they have been employed as clerks in the government offices in Washington.

In this country the agitation may be said to have been set in motion almost entirely by John Stuart Mill and Mrs. Taylor, the lady who afterwards became his wife. She published in 1851 an article in the *Westminster Review*, which ably and powerfully directed attention to the question, and since then the cause of female suffrage, education, and professional activity has steadily advanced through much ridicule and obloquy, gradually gaining influential adherents, and becoming more and more popular with the general public. The political branch of the agitation is less flourishing than the others. A petition for the abolition of the electoral disabilities of women was presented to the House of Commons in 1866, and on May 2d, 1867, John Stuart Mill moved an amendment to the Reform Bill in favour of female suffrage, which was negatived by 196 to 73. The bill for the same object which is brought forward annually by Mr. Jacob Bright, Mr. Forsyth, or Mr. Courtney is always rejected by a large majority. In 1871 it was lost by 220 to 157 votes; in 1872 by 222 to 143; in 1873 by 222 to 155; in 1874 it was withdrawn; lost in 1875 by 187 to 152; in 1876 by 239 to 152; 'hustled out' in 1877; and lost by 219 to 140 in 1878. Thus, though the minority in favour of the bill cannot be said to increase, the interest which the question excites is shown by the comparatively large number of votes given on each side. Meanwhile agitation outside Parliament has been actively carried on. The National Society for Women's Suffrage held its first annual meeting at Manchester on the 30th October 1868, and has issued numerous tracts and pamphlets for the dissemination of its opinions. A monthly paper called *The Woman's Suffrage Journal* is published in Manchester under the editorship of Miss Lydia Becker, and opinions favourable to W. R. are also advocated by *The Englishwoman's Journal*, published in London. It is impossible to refer to the numerous papers on the subject to be found in all the leading magazines and reviews, for the most part from the pens of Mrs. Fawcett, Mrs. Hill, Miss Becker, Miss Frances Power Cobbe, and Miss Helen Taylor. The admission of women to the municipal franchise (1869) was a step in advance, as was also the Education Act of 1870 (Scotland 1872), which not only gave women a vote in the election of school-boards, but made them themselves eligible. Mrs. Garrett Anderson and Miss Davies were returned by an immense number of votes to the first London school-board, and the example of the metropolis was followed by Manchester, Edinburgh, and several other large towns.

Much more progress, however, has been made towards throwing off educational and industrial disabilities than towards acquiring political rights. The higher education of women is being promoted by institutions ranging from such establishments as Girton College, Cambridge (two similar colleges have just been founded [1879] at Oxford), down to the Girls' High Schools established in different quarters of London. In 1869 the University of Cambridge established periodical local examinations throughout the country to encourage and test the progress of female education, and the example has been followed by several other universities. In 1878 the University of London obtained a charter empowering it to grant degrees to women, who are now admitted to all classes at University College. The Medical Act of 1876 permitted the registration of women, and there are now many students at the Medical School for Women founded in 1874. A large number of students, however, go abroad. The medical school of the University of Zürich has since 1864 been largely frequented by female students. The University of Paris also grants medical diplomas to women; while the German Universities, notably Berlin and Vienna, afford considerable facilities for private instruction. In the industrial arts, too, women are rapidly forcing their way, while their employment in post and telegraph offices, &c., and even in commercial occupations, is becoming more and more common. The 'lady-help' idea, recently so much discussed, is an invention not so much of the supporters of so-called W. R. as of their opponents, who hold domestic occupation to be the only natural sphere for female activity.

On the Continent the question of W. R. has been a good deal mooted, though not so actively as here and in America. In France the movement has never taken very strong hold. *L'Avenir des Femmes* is the name of a paper published in Paris for the discussion of questions connected with W. R., and several attempts have been made to get up an active agitation, but for various reasons Frenchwomen as a body stand even more aloof from the movement than the women of most other countries. In Switzerland women vote in every canton, and the opinions of the advanced party are represented by a paper, *Le Droit des Femmes*. In Italy there are two papers advocating W. R.—*La Donna*, published in Venice, and *La Cornelia* in Florence. There has been a good deal of agitation on the subject in Germany, Den-

mark, and Russia; but in these countries 'emancipated' women, as they are called, are looked on with even less favour than in English-speaking lands. A newspaper, *Das Frauenwelt*, is published in Berlin. In Sweden women have a right to vote on certain questions, and are admitted to the University of Upsala. See Mary Wollstonecraft's *Vindication of the Rights of Women* (Lond 1791); J S. Mill's *The Subjection of Women* (Lond. 1869) and his *Dissertations and Discussions* (Lond 1859-67); Margaret Fuller Ossoli's *Woman in the Nineteenth Century* (New York 1845; revised 1855); L. M. Child's *History of the Condition of Women in all Ages and Nations* (New York 1845; 5th ed. 1854); M. J. Woochang', a town in the interior of China, province of Hu pe, on the Yang-tse kiang, opposite the important trading town of Hankow (q. v) It stands amid cotton-plantations and rice-fields, and is a great emporium for tea, which is exported to Britain *via* Shanghai. Hankow is virtually a suburb, and another considerable section of the town on the N bank of the river is Hang-yang fu. The pop of W., including the outlying portions, is estimated at 1,000,000

Wood, in a botanical sense, consists of the hard, solid, non-succulent stem of any plant, and chemically it consists of lignin, a hardened form of cellulose, the principal constituent of all vegetable life, with a small proportion of resinous and incrusting matter W. thus only differs from vegetable fibres—cotton, flax, hemp, &c —in its physical condition. Woody stems are divided into two great classes, according to the manner in which they grow The first and most important class is the exogens or exogenous stems, so called on account of the annual increments being added on the outside of the stem just within the bark, and the layers of growth are seen in such stems in a series of concentric circles, each ring of which represents the growth of one year. This class embraces all the trees of temperate climates, and, indeed, the greater part of all tree life. The second class —endogenous stems—shows no rings of annual growth, but a cross section exhibits a series of dark spots, more or less closely studded, and always more densely packed towards the outer circumference. There is no proper distinction of bark and W; increase of size takes place by pressure from the centre outwards, and the outer portions of the stem are always hardest and most compact. The principal representatives of endogenous woody stems are the palm-trees and the bamboos, but although these are largely used for structural and other applications of W., especially in the countries of their production, they are not to be compared for general utility with exogenous stems. The spurious stems of acrogens (tree ferns) have no place as sources of W. In an exogenous stem the W. is divided into an outer sap-W. or albumen portion and an inner heart-W. or duramen part. As a rule, it is only the heart-W. of a tree that is useful for the ordinary purposes of W., and the rate at which the sap-W. turns into heart-W. varies much in different species of tree. All kinds of W. are subject to many defects, which decrease their usefulness for building and other purposes. The principal defects are known as 'shakes'—a heart-shake consisting of clefts or fissures running through the centre of the W. across the pith; cup-shakes radiate from the centre or go round the lines of annual growth. Knots and warpings are also common defects, the former being especially characteristic of several kinds of pine-W. For trade purposes W. is classified under two heads, as soft W. and hard W., the leading representatives of the former being the numerous varieties of pine, and the latter embracing the oaks, beeches, ash, birch, and furniture-woods generally. Dye-woods form a class by themselves, and belong to a quite distinct trade. W., before it can be properly used for any structural purposes, must be seasoned by some means of drying, so as to withdraw the vegetable sap from it. The common and best way of seasoning is to stack the W. in the open air, but this process is tedious, especially with large logs and hard W. Submergence in water for some time hastens the seasoning operation, and steaming or boiling also render W. quickly fit for employment, although it weakens the timber. A process of desiccation in heated chambers is practised for the seasoning of thin planks and boards used by joiners and cabinetmakers, but such rapid seasoning is very ready to cause a splitting and warping of the W. Partly to season and partly also to increase the durability of W. in certain very exposed situations, various ways of treating timber with preserving agents are employed. One process, largely used for railway-sleepers and similar purposes, consists in impregnating the W. under strong pressure with creosote or impure carbolic acid. The process having been originally introduced and patented by the late John Bethell, is now known as Bethell's process. Bennett's process has also been extensively used, especially on the Continent. It consists in impregnating the W under pressure with the chloride of zinc (Burnett's fluid). Kyanising consists in treating the W. with Kyan's preserving fluid, a solution of the bichloride of mercury It is a process little used in England. Boucheri's process, which has been adopted to some extent in France, consists in causing the tree trunk to absorb a preservative solution—acetate of copper or acetate of iron—through its roots in the same way as it takes up and circulates sap while in life. The tree is felled and the root end is dipped in the proper solution, which then is carried through the trunk and supplants the ordinary sap. The process is not so well adapted for firs, oaks, ashes, and poplars as for such trees as the lime, beech, willow, alder, and elm There are several other preservative processes and solutions which have been brought forward but little used. Besides its multifarious applications as timber in engineering, shipbuilding, carpentry, and cabinetmaking, W. has numerous important minor uses. It is a most valuable fuel, and the source of W-tar, pyroligneous acid, W.-naphtha, and charcoal; and certain kinds of W are now extensively pulped for employment as papermaking materials.

Wood, Distilla'tion of. See DISTILLATION

Wood, Anthony, was born at Oxford, 17th December 1632, entered Merton College (1647), took his bachelor's degree (1652), and that of master (1655) His life was spent in laborious antiquarian research, illustrative of the history of his university. W died 29th November 1695. In 1674 appeared *Historia et Antiquitates Universitatis Oxoniensis* (2 vols. Lond 1674), a translation into Latin by Peers, a student of Christ Church, of W's English treatise on the subject. The first volume is devoted to the university, and the second to the particular colleges. Peers' version was so arbitrary and inexact that W. almost refused to own it. The English original, carefully edited by the Rev. John Gutch, was published at London (5 vols. 1786-96). Other works of W.'s are *Athenæ Oxonienses: An exact History of all the Writers and Bishops who have had their Education in the most Ancient and Famous University of Oxford from* 1500 *to* 1690, *with the Fasti or Annals of the said University* (2 vols. Lond 1691-92). A second edition of this by Tanner, with important additions, appeared in 1721, and a third, with continuation by the Rev. Philip Bliss, D.C L, Fellow of St John's College, Oxford (4 vols 1813-20) A fourth edition, projected by the Ecclesiastical History Society, only reached a first volume, containing, however, a *Life of W.* (1848) by Dr. Bliss. Though a man of mean capacity and narrow mind, W. possessed an inexhaustible industry, and accumulated vast stores of valuable knowledge See Mark Pattison's *Chapter of University History* in *Macmillan* (July-August 1875).

Wood, Sir Andrew, a famous Scottish admiral, was born about the middle of the 15th c., probably at the Old Kirkton of Largo in Fife. Originally a merchant trader of Leith, he learned the art of naval warfare by frequent encounters with pirates in defence of his ships and merchandise. James III. often employed him in honourable missions. In 1481 he defeated an English squadron in the Firth of Forth, and in the same year gallantly defended Dumbarton against the fleet of Edward IV.

His two ships, *The Flower* and *The Yellow Carvel* (each about 300 tons), made frequent voyages to the Dutch and Hanse towns, exchanging 'the wool and hides' of Scotland for 'the mercery and haberdashery ware' of the Continent. In 1482 he received as a reward of his services the honour of knighthood, and the lands and village of Largo in fee. W. was strongly opposed to the rebellion of the nobles against James III., kept close by in the Forth with his ships while the battle of Sauchieburn was going on, and for some time after the murder of the king refused to acknowledge the new government. In 1489, however, the appearance of a piratical English squadron in the Firth of Forth induced him, on the urgent solicitation of James IV., to place his services at the disposal of that monarch. He engaged the enemy off Dunbar, and captured every ship. On the 10th and 11th of August 1490, off the Isle of May, he won a brilliant victory over a skilful English commander, Stephen Bull, whom he carried with his three ships into the port of Dundee. Fresh honours and gifts of lands and superiorities followed these achievements. In 1503 W. was employed to chastise the rebels in the Hebrides. In 1511 he was put in temporary command of the *Great Michael*, built by James for the protection of Scotch commerce, and deemed the strongest ship then afloat. After Flodden he was sent to France to invite the Duke of Albany to accept the regency. His naval career was now over, but he was several times employed in court service. There is a story that he had a canal cut from his house in Largo down to the parish church, and that he used to sail thither in his barge every Sunday. He died about 1540. See the *Histories* of Pitscottie and Buchanan, and in modern times those of Tytler and Burton.

Wood'bine. See Honeysuckle.

Wood'bridge, a river-port of Suffolk, England, stands on the tidal Deben, 8 miles E.N.E. of Ipswich by rail. Its church of St. Mary, a fine Perpendicular flint-work structure, with a tower 180 feet high, was restored and enlarged in 1875; other edifices are St. John's (1845), the sessions-house (1587), a lecture-hall (1851), and the Seckford almshouses and grammar-school, two richly-endowed charities founded in 1587 and 1662, but amalgamated in 1861, when handsome new buildings were erected. In 1878 there entered the port 841 vessels of 48,286 tons, and cleared 804 of 47,866; the imports (coal and timber) amounting in 1877 to £21,464. Brick-making, ship-building, malting, and iron-founding are carried on, and W. publishes one weekly newspaper. Pop. (1871) 4403. Crabbe was apprenticed to a W. surgeon (1771); and at W., Bernard Barton, the 'Quaker poet,' lived and died (1806–49).

Wood'bury Pro'cess, a photo-mechanical printing process, in which an image obtained in relief on hardened gelatine by the agency of light is made by pressure to yield an intaglio impression on a lead plate, from which prints are thrown off in a press. This process, which gelatinised Indian ink, takes its name from Mr. Woodbury, the inventor, is extensively used for book illustration, being worked in London by the Woodbury Company, and—under the name *photoglyptie*—in Paris.

Wood-Carving. See Carving.

Wood Charcoal is the impure carbon obtained by the decomposition of vegetable matter by heat without free access of air. It may be produced from almost every kind of wood. Of British trees the beech, sycamore, ash, thorn, oak, birch, and alder are well adapted; the holly and yew, particularly the latter, make a very superior description; the elm, Spanish chestnut, and lime require to be peeled before charring; and there is an antipathy to the fir and other resinous trees. W. C. was formerly always made in a kiln in the open air. In this process the wood is cut into proper lengths and duly arranged in piles or stacks, it being of great importance to pack the wood close. The heap is then covered with turfs and the kiln lighted. Day and night the watch must be kept on the movements of the fire, until all the volatile constituents of the wood have been expelled, and the charcoal remains. Four to six tons of wood by this plan are required to produce one ton of good charcoal. But W. C. is now by preference made in large cylinders or retorts. By this process the charring takes place in about sixteen hours. The general properties of W. C. are, that it is black, sonorous, and brittle, and retains the form of the wood from which it is obtained; it is insoluble in water; infusible and fixed in the most intense heat; it is generally a bad conductor of heat, but conducts electricity; it absorbs various gaseous bodies, and has considerable antiseptic powers. The fumes given off by burning charcoal are poisonous. The charcoal made for medicinal purposes must be obtained from woods containing a small percentage only of mineral matter, such as willow. It is employed chiefly in the form of poultice to destroy the fœtor of sores and ulcers, also as a dentifrice, and is occasionally administered internally in dyspepsia. The important uses of W. C. are as a fuel and as an ingredient of gunpowder.

Wood'chat, or **Woodchat Shrike** (*Enneoctonus rufus*), a species of Shrike (q. v.) of rare occurrence in Britain, but common on the Continent. It is of a chestnut red on the head and neck, the back being black and white, relieved by brown tints. The under parts are white. The two central feathers of the tail are black, and the two outer feathers white. The eggs are a bluish white, speckled with dusky brown.

Wood'chuck (*Arctomys monax*), a species of Rodent animal allied to the Marmot (q. v.) and found in North America. Its average length is 16 inches, and its colour a blackish brown. It burrows in the ground, hence its familiar name of 'ground hog.' In winter it hybernates.

Wood'cock, a general name applied to different species of Wading Birds or *Grallatores*, allied to the *Snipes* (q. v.) or *Scolopacidæ*, and included in the *Longirostral* section of the waders—a group distinguished by having long bills grooved from the nostrils. The great toe is short, or may be absent altogether. The Common W. (*Scolopax rusticola*) has long been famed as a table delicacy. This bird attains a length of about 12 or 14 inches, and a weight of from 10 to 15 ounces. The general colour is a brown above, varied with darker tints, while the under parts are barred with dark brown. The tail is black tipped with grey. The W. is migratory, and arrives in Britain in March or April. In habits it is peculiar, appearing after mid-day, and feeding in early morning and at dusk. Its food consists of worms, for the capture of which its long bill is admirably adapted. The W. is wary and shy, and considerable experience is needed for its capture. The eggs are four, and are of a brownish-white colour blotched with brown. The mother W. is said to carry her young to the feeding-grounds. Large numbers are trapped by cleverly arranged nooses. The American W. (*S. minor*) is rather smaller than its British neighbour, attaining a length of 11 inches. It occurs almost universally throughout N. America.

Wood'-Engraving, or **Xylog'raphy**, is the art of producing designs on wood having lines or parts in relief, of which impressions may be obtained in an ordinary printing-press. A W.-E. or *woodcut*, which has its *whites* scooped out or cut away, and its *darks* standing in relief, is the reverse of a copper or steel plate engraving, in which the *darks* are represented by incisions or corroded parts, and the *whites* by the untouched surface of the plate. To obtain a print of a copperplate engraving involves a tedious process of inking and a special press (see Engraving), but a woodcut may be wedged in a chase with type, and an impression of both procured at the same moment. Woodcuts are therefore extensively employed for illustrating books and periodicals; and but for the invention and cultivation of W.-E. our vast illustrated literature—a salient feature of nineteenth-century civilisation, and a most important educational agent—which was pioneered by the *Penny Magazine* (1832) and the *Illustrated London News* (1842), could not have been possible.

The principle of W.-E.—that of taking impressions from inked wood blocks—was well known in Europe during the 13th and 14th centuries, and was applied in the attestation of documents by impressing monograms or cyphers thereon, and in stamping coloured designs on smooth surfaces, as of silk. The origin of W.-E. has been ascribed to the Chinese; but while it is indisputable that the latter produced printed books by means of engraved wood blocks at a period long anterior to the application of the principle by Europeans, it is believed that the latter did not acquire their knowledge from the East, but independently invented the art. The origin of printing is intimately associated with the invention of W.-E. in Europe. Early in the 15th c. the wood-engraver's art was applied in Germany to the production of images of saints, called *Helgen* or *Helglein*, a corruption of *Heiligen*, and playing-cards. The outlines only of the figures were carved on wood, and the prints on paper were afterwards

coloured by hand or stencil. The earliest known dated print is that of St. Christopher (the 'Christ-bearer'), which was discovered, pasted to the cover of a MS., in a convent at Buxheim, near Memmingen, in Suabia, and which is now in the possession of Earl Spencer. It bears the date 1423, admittedly genuine, and represents the saint traversing an arm of the sea and carrying the infant Saviour. The print is rudely executed, but internal evidence is afforded that it was not the first of its kind. The next step in advance was the cutting of pictures with explanatory texts on the same block, and a connected series of prints of these blocks form what is known to bibliographers as 'block-books.' The prints were obtained by rubbing a burnisher over the paper laid on the engraved block. Entire pages of text alone were then cut on blocks, and eventually the art culminated in the invention of movable types and taking impressions therefrom by means of a press (see PRINTING). Woodcuts were universally employed to illustrate books printed from movable type, and a Psalter printed on vellum by Faust and Schöffer at Mainz in 1457 is a famous example of the early combination of typography and W.-E., the large initial letters, beautifully ornamented, being printed in two colours. Caxton's second edition of the *Game and Playe of Chesse* (published in 1476) is the earliest specimen of an illustrated book in the English language. Towards the close of the 15th c. and early part of the 16th c. the art of W.-E. was brought to a high pitch of excellence by German masters, including Albert Dürer (q. v.), Hans Burgmair, Hans Schaufelein, Lucas Cranach, Lucas van Leyden, and Hans Sebald Beham. Dürer's illustrations of the *Apocalypse*, the *History of the Virgin*, *Christ's Passion*, and other works, are marked by beautiful and accurate drawing, a refinement of *cross-hatching* (an expedient introduced about 1486 of representing shadows and varied tints by intersecting lines), and wonderful pictorial effects. Under the patronage of Maximilian I. several works were issued illustrated with magnificent woodcuts executed by Burgmair, Schaufelein, and Dürer; and in 1538 there was published at Lyon, Hans Holbein's *Dance of Death*, illustrated with small pictures displaying remarkable skill in execution. *Chiaroscuro*, or the imitation of artist's drawing by printing in sepia, Indian ink, or other colours from several engraved blocks, was practised at this period, having been first introduced by Lucas Cranach. About the close of the 16th c. the art of W. E. began to decline in Germany, and in the succeeding century it also lost its artistic character in Italy, France, and the Low Countries, where it had been cultivated with considerable success. It was reserved for the father of English W.-E., Thomas Bewick (q. v.), to revive the neglected art, and to give it that vigorous impulse which has carried it to the high position it now occupies. Bewick introduced new resources into the art, and applied them with graceful and graphic effect in illustrating his works, the best of which are his *British Quadrupeds* (1790) and *British Birds* (1804). Of other English wood engravers who contributed to raise the art to its present state of perfection may be mentioned Nesbit, Clennel, Harvey, Branstone, Thomson, and Jackson.

Boxwood is, from its density and tenacity, the only wood suitable for W.-E. For common work pear and sycamore are in favour, and recently a process patented in 1876 for hardening wood so as to rival boxwood has met with some consideration. The boxwood is cut across the grain in slices of a thickness exactly equal to the height of type with which it, or a facsimile in metal, is wedged in printing. The slices are of small size, and for large 'blocks' several pieces are joined together by screw-bolts. After the drawing has been made on the block, the component parts may be distributed among several engravers for rapidity of working, and in such a case the parts when brought together again are touched up by one hand. The wood is coated with a preparation of Chinese white for the artist, who draws his subject thereon in pencil and washes of Indian ink. The engraver then proceeds to give expression to the artist's drawing by means of tools which mainly consist of angular-edged *gravers* and *tint-tools* of several sizes, adapted for rendering a great variety of tints, clouding, cross-hatching, graduated distances, &c., and *gouges* for cutting out intervals. Proofs of the work in progress are taken by hand with the aid of a *burnisher*. Stereotypy and electrotypy are taken advantage of in procuring duplicates of woodcuts, and photography has been utilised in transferring pictures to the block ready for engraving. Mr. A. E. Smith of London has recently perfected a photographic process of wide adaptation, called the *cryptotype*, which entirely dispenses with drawing. Wood-blocks are combined with metal plates and lithographic stones in the production of colour-prints, such as are issued by the *Illustrated London News*. Several substitutes for W.-E. have from time to time been proposed. The *Graphotype* (q. v.) has met with some measure of success for common work; and engravings, pen-and-ink drawings, &c., are now extensively reproduced in the form of surface-blocks to be set up with type, by means of photo-typography—a development of Pretsch's swollen gelatine process (see PHOTOGRAPHIC ENGRAVING).

Wood' Louse (*Oniscus*), a well-known genus of *Isopodous* Crustaceans (see ISOPODA), the species of which are commonly known as 'Slaters,' and are found beneath stones, the bark of trees, &c. The legs number seven pairs, and are attached to the thoracic segments. The segments of the abdomen are coalescent, and form a broad caudal shield. The W. L. is of a leaden colour. Allied genera and species are the Sea W. or Sea Slater (*Ligia oceanica*), and the *Porcellis scaber* is another species to which the name is often applied.

Wood'pecker (*Picus*), a genus of birds representing the family *Picidæ*, or that of the W. and Wryneck (q. v.). In these birds the tongue is extensile, and is provided with barbs and with a viscid secretion perfectly adapting it for the capture of insects. The bill is strong and wedge-shaped, and the claws are hooked. The feathers of the tail are pointed and stiff, and aid these birds in climbing and in fixing themselves on the trunks of trees. The toes are directed two forwards and two backwards, as in other *Scansorial* or climbing birds. The W. inhabits both hemispheres. Five species are British in their distribution. The Great Spotted W. (*Picus major*) attains a length of 9 inches. Its plumage is black and white, the top of the head being scarlet and the under parts white. The female wants the red hue on the head. The Green W. (*P. viridis*) attains a length of 10 or 12 inches. It is dark green above, tinted with yellow; the tail is black, and the under parts are ashen green. The head bears a scarlet crown. The other British species are the Great Black W. (*Drycopus martius*), the Northern three-toed W. (*Picoides tridactylus*), and the Lesser Spotted W. (*Picus minor*). Of American woodpeckers the Downy W. (*Picus pubescens*) is a familiar example. It is of a scarlet colour on the back, velvet black on the head, with a white streak over the eye. The under parts are white. The average length of this bird is 7 inches; its popular name of 'Downy W.' being derived from the loose feathers in the middle of the back. The Ivory-billed W. (*Campepholus principalis*) also inhabits N. America, and is so named from the extremely long ivory-like beak with which it is provided. It attains a length of 20 inches, and is of a black colour, tinted with a metallic green. A scarlet crest is borne on the black head, and the neck is marked with white. The bill is of an ivory hue, and may measure fully an inch in breadth at its base. The Red-headed W. (*Melanerpes erythocephalus*) of America is one of the best-known birds of the New World. It measures from 8 to 10 inches, and it is of a black colour, with a scarlet head and neck; the upper tail-coverts and under parts are white. The beak is blue, and the legs and feet greenish. Of the Ground W. the best-known species is the Gold-winged W. (*Colaptes auratus*) of America. This species destroys enormous numbers of ants of all kinds. Its length is about 12 inches, and its colour is grey and amber above, the throat reddish, and the abdomen yellowish, spotted with black. The inner aspects of wings and tail are a golden yellow.

Wood Oil, an oleo-resinous liquid obtained from several trees of the genus *Dipterocarpus*, growing in Eastern Bengal, Chittagong, Pegu, and some of the islands of the Indian Archipelago. It is extracted by making deep incisions in the trunk and laying fire therein. Some trees yield from 30 to 40 gallons in one season. W. O., or *Gurjun balsam* as it is also called, resembles copaiba balsam in medicinal properties, and in India is substituted for it. The Malays use W. O. as a varnish, and apply it instead of tar to seams of boats, &c., and to timber to preserve it from the ravages of the white ant. The W. O. of China is an entirely different substance from the foregoing, and consists of a fatty oil expressed from the seeds of *Aleurites cordata*. This oil is also used for varnishing and preserving wood, for mixing with pigments, and in medicine.

Wood'ruff (*Asperula odorata*) is a perennial herb, allied to the Bedstraw (q. v.), of wide distribution, entering into the flora of most countries of Europe, the Mediterranean region and W. Asia, and is a common plant of shaded hedge-banks, copses, &c., in the British Isles. It does not possess any economic value, but is notable for possessing the agreeable fragrance of cumarin during and after drying (see VERNAL GRASS). The genus *Asperula* numbers about 50 species, natives of temperate regions throughout the world. The root of *A. tinctoria* has been used as a substitute for madder, and *A. cynanchica* bears the name of 'Squinancy-wort' from its supposed efficacy in curing the quinsy.

Woods, For'ests, and Land Rev'enues, Commis'sioners of. Act 10 Geo. IV. cap. 50 consolidates previous Acts relating to the management of the Crown lands. They are placed under the management of the Commissioners of Woods and Forests, who are under control of the Treasury. Act 2 and 3 Will. IV. cap. 112 empowers the Treasury to transfer to the C. of W. and F. the management of the Crown lands of Scotland. The alterations made by 29 and 30 Vict. cap. 62 relate to points of detail. The yearly receipts amount to about £320,000. See CIVIL LIST, CROWN LANDS.

Wood Sorr'el. See OXALIDACEÆ.

Wood'stock, a market-town of Oxfordshire, on the Glyme, 7 miles N.N.W. of Oxford by rail, has a chapel mostly rebuilt in 1785, but retaining fragments of 12th c. work. The glory of the place is Blenheim Palace, in whose park, laid out by Capability Brown, the tiny Glyme is spanned by a mighty bridge, then widens into an artificial lake, while the trees are ranged as were the troops at Marlborough's victory. The palace itself, designed by Vanbrugh, covers 7 acres, and is a heavy, imposing pile, with rich art-collections, though its 'Titian Gallery' was destroyed by fire in 1861. Glove-sewing is the leading industry of W., which returns one member to Parliament, the pop. of the borough being (1871) 7477. The legends of Fair Rosamond's labyrinth and murder by Queen Eleanor, of Ælfred's and Chaucer's residence at W., must be abandoned; but as a royal manor from immemorial times W. has played its part in history. Here Æthelred held a *gemót*, Malcolm and Rhys paid homage, Edward the Black Prince was born, and Elizabeth was kept in ward by Mary. Here, too, the 'just Devil' disturbed the Parliamentary commissioners, as told in Scott's romance, and Rochester made an edifying end. Lastly, in 1704 came the grant to the victor of Blenheim, and the ruthless demolition of the ancient manor-house. See Marshall's *History of W.* (Oxf. 1873).

Wood' Swallow (*Artamus sordidus*), a species of Dentirostral bird not allied to the Swallow (q. v.), but related to the Shrike (q. v.). It is an agile, active bird, with pointed wings and a square tail. The best-known specimen is the Sordid W. S. found in Australia. It is black above and white below, and attains a length of 3 or 4 inches. An allied species is the Cinerous W. S. (*A. cinereus*) of Tasmania, so named from its dusky hue. The former is notable for its habit of massing itself together in numbers on the branches of trees in a fashion reminding one of the swarming of bees.

Wool is a modified form of hair, its distinguishing characteristics being greater fineness of fibre, the individual fibres are more or less waved or curled, and generally colouring matter is absent and the W. is white, although grey, brown, and black colours are found among wools. Further, when examined under the microscope, W. is seen to be much more scaly or imbricated in structure than common hair, and on that peculiarity its property of felting—one of its most valuable qualities—depends. In chemical composition pure W. is similar to hair and other epidermic products, the following being the percentage of substances present: carbon, 50·65; hydrogen, 7·03; nitrogen, 17·71; oxygen and sulphur, 24·61. Unwashed or raw W., however, contains a large proportion of mineral matter, and a fatty substance termed suint (a compound of a fatty acid, with potash) which are soluble in, and can be removed by washing with cold water. The proportion of matter other than pure W. in unwashed W. may amount to as much as 75 to 80 per cent. of its total weight. W. is the most important and extensively used of all fibres next to cotton, and indeed the term may be held to embrace all animal fibres in use, except silk. Although most largely derived from the numerous varieties of sheep, W. is also obtained from the Alpaca (q. v.) and allied species found in S. America, from the camel, the mohair goat, and the Cashmere goat of the Himalayan plateaus, whence the W. for the famous Cashmere shawls is obtained (see PASHMINA). W. comes into commerce in two distinct forms (1) as fleece W., and (2) as skin W. The former is obtained by the annual shearing or clipping of sheep, which in the United Kingdom takes place about the end of May. The fleece yielded by a sheep may vary in weight according to breed and local circumstances from 4 or 5 lbs. up to 8 or 9 lbs. Each fleece is made up of several distinct qualities of W., but it is generally sent into the market as it is clipped, the work of assorting qualities being afterwards performed by staplers. Lamb's W. differs from the W. of full-grown sheep in being softer and more delicate to the touch. Skin or pulled W. is obtained from the skins of slaughtered sheep, or of animals which have died a natural death. It is inferior in lustre, strength, and elasticity to fleece W. Among the many methods of classifying W., an invariable distinction is established between short or carding W. and long or combing W. Carding wools, which besides being shorter in the staple, more waved or curled, and more strongly scaled or imbricated than combing varieties, are represented by the W. of the merino sheep (see MERINO), a peculiar breed originally confined to Spain, but in the 18th c. introduced into Germany, and now bred in the Australian colonies, the Cape of Good Hope, and certain parts of S. America. Combing wools or worsted wools, so called on account of the manner in which they are prepared and the use to which they are put, are in the trade separated into combing kinds and carpet and blanket kinds. Under these heads are embraced all the long, comparatively coarse and straight wools, as well as alpaca and mohair. The raw materials of the W. trade are now supplemented to no inconsiderable extent by 'shoddy' and 'mungo' (see SHODDY), obtained from woollen rags, and mixed with raw wools for spinning into certain classes of fabrics. The regions in which sheep are grown largely on account of their yield of W. are vast, wide-spread, and most varied as to climate, and consequently the W. markets draw supplies from many quarters. The annual consumption of W. is enormous, and has been roughly calculated to 2,233,500,000 lbs. The United Kingdom is the largest consumer of W., and in addition to the native supply, estimated at about 155,000,000 lbs. annually, enormous quantities are imported from Australia and New Zealand, from the Cape of Good Hope, the River Plate, and from India, and smaller quantities are obtained from numerous other sources. The increase of the W. trade from Australia especially, but also from the Cape and the River Plate, has been marvellously rapid. In 1831 less than 2,500,000 lbs. of W. came from Australia, and the amount from the Cape did not reach 50,000 lbs. The following table shows the weight in millions of lbs. of pure washed carding W. produced in these regions during recent years:—

	1860	1871	1873	1875	1877	1878
Australia . .	35	107¾	109½	136¾	159	150½
Cape	14¾	30¼	32½	35	34	32¾
River Plate .	15½	74½	83½	70½	77¾	72¼
	65¼	212½	225½	242¼	270¾	254¾

The following statement, compiled by the eminent W. brokers, J. L. Bowes and Brother, of Liverpool, shows in a most compendious form the movements and progress of the trade during recent years. The figures are given in millions of lbs. :—

	1855	1862	1869	1877	1878
Receipts of all kinds of Sheep's W. into England	97¾	168¾	255¼	406	395½
,, ,, Alpaca	1½	2¾	3¼	3½	3¾
,, ,, Mohair	2¾	3¼	4¾	8¼	7
,, ,, Rags (for shoddy) .	5¼	29¼	37½	75	72¼
Weight of W. grown in England	140	140	155	155	155
Total supply	247¼	344	[illegible]55¾	647¾	633½
Exported	45½	58¼	129	197	205½
Retained in England. .	201¾	285¾	326¾	450¾	428
Percentage retained	81⅝	83	71¾	69⅝	67½
,, exported	18⅜	17	28¼	30⅜	32½

The fluctuations in value of certain standard qualities of W.

since 1860 are shown in the subjoined statement. The figures represent pence per lb. :—

	1860	1863	1866	1869	1872	1875	1878
Port Philip washed (carding)	24	23	22¼	17	27	22½	19½

East India, best soft (carpet)	14	16	14½	11	17½	14	9½
Alpaca Islay fleece . .	27½	30½	38	28	30	30	17
Mohair Turkey fleece .	35½	36	44	45¾	40½	43	23

Wooll'en and Wor'sted Manufac'tures. The industries connected with wool are among the earliest, and they were at one time the most important, of English manufacturing industries; and indeed they continued to be the greatest of British textile manufactures till the enormous development of the cotton manufacture about the beginning of the 19th c. took place. The wools of England were in the Middle Ages accounted the best in Europe. The manufacture of woollen cloth is supposed to have been established in England during the Roman period, but there is no evidence to fortify this conjecture. At the time of the Norman Conquest, Flemish weavers came to England, but the first effective impetus to the industry was given in the reign of Edward III., when seventy families of clothworkers from the Low Countries settled in England. At that period the worsted manufacture was already established in Norwich, and whether the name of the manufacturing town, Worsted, in that county, is derived from the industry, or the trade named after the town, is a point not quite settled, although the former is the more probable theory. Many curious legislative measures were from time to time passed with the view of fostering W. and W. M., and some of these Acts of Parliament remained unrepealed till this century, a law prohibiting the export of English wool only having been repealed in 1824. The dyeing, spinning, and weaving of woollen fabrics was a domestic industry spread throughout the entire country till almost within the memory of persons now (1879) living; but for a long period special departments of manufacture have been gravitating towards the well-recognised centres in which they are now established as great factory industries.

Woollen manufactures include the preparation of all kinds of cloth made with short wool, the yarn from which is prepared by carding, and the cloth is always close in texture, and partially felted in finishing. Broad cloths, doeskins, Meltons, beavers, diagonals, Venetians, and tweeds, are all examples of woollen manufactures. *Worsted* manufactures have to do with long-staple wools, prepared for yarn-spinning by a process termed combing, and woven into hard-spun lustrous textures used for ladies' wearing known as 'Bradford goods,' such as lustres, cords, moreens, camlets, &c., and reps, merinoes, worsted damasks for hangings, and numerous other more or less fanciful and fleeting classes. Carpets and blankets are also examples of worsted fabrics, although these are regarded as distinct branches of trade, and so also are the worsted hosiery and knitting worsted trades. Felting is avoided in all the branches of the worsted manufacture. The classes of wools used for these distinct trades have already been indicated under WOOL (q. v.); but it may here be said that the wool of different portions of one fleece may be stapled out for use in both these departments of industry. The processes employed in the woollen manufacture will here be first indicated, and thereafter, so far as they differ, the stages in the worsted manufacture will be sketched.

In the preparation of woollen yarn the following are the essential processes, beginning with unsorted raw wool. 1st, stapling; 2d, scouring; 3d, drying; 4th, willowing; 5th, oiling; 6th, carding; 7th, condensing; and 8th, spinning. The object of the 1st process, *stapling*, is to arrange the whole of the wool into uniform qualities, each fleece, as already mentioned, yielding several different qualities as regards fineness and length. The work was formerly much carried on as a separate trade by staplers, but now many of the large manufacturers staple their own wool. *Scouring* is essential for removing suint and all extraneous matter which attaches even to well-washed wool. It is done in long tanks supplied with a constant flow of hot alkaline water, admitted pure and clean at the opposite end of the tank from that at which the wool is thrown in. The tank is fitted with a series of bars, on each of which a line of long spikes, which, moving through half a circle within the water, carry the wool gradually forward through the tank. In this way the dirty wool enters the water where it is dirtiest, and as it passes on gradually losing its impurities it meets water proportionately less impure, till at the end where it is removed from the tank the now well-washed wool is submitted to water just entering the tank, and consequently perfectly clean. From the tank it is passed between a pair of squeezing rollers, thereafter sometimes rinsed in pure water, and thrown in an open fleecy state on a drying machine, which consists of a sloping perforated copper cover placed over a series of hot pipes through which air is blown. The *willowing* or *devilling*, which follows this operation, has for its object the opening out of the wool to a uniform mass, and the removal of 'burrs' and any mechanical impurities which still remain in the wool. In some kinds of wool the presence of burrs or closely matted seeds, &c., is the cause of serious annoyance, and special burring machines must be used to free them from these entanglements. At this stage also wool intended for the manufacture of wool-dyed goods, as opposed to yarn-dyed or piece-dyed fabrics, is dyed. It is only, however, the fastest and most enduring dyes that can be used, as inferior colours would be injured by the 'milling,' and other operations through which cloth passes ere it is finished. Consequently it is only the finest and most valuable cloths that are wool-dyed. Wool after scouring has lost all its natural oil, and in that way becomes harsh, dry, and brittle. It therefore is necessary before submitting it to the carding and subsequent operations to give it some amount of freedom and suppleness, and that is done by *oiling* the fibre. For the finer wools olive oil or earth-nut (*Arachis hypogæa*) oil is used; but fish oil, rape, cotton-seed, and lard oil, &c., are also largely used. The *carding* which follows is an operation for which generally two carding engines or machines are used; 1st, the scribbling card or scribbler, and, 2d, the finishing card or finisher. The carding machines consist of a series of revolving rollers or cylinders covered with leather or vulcanised india-rubber studded with innumerable teeth of bent steel wire. These cylinders revolve in different directions, and as the one carries the material operated on from the other, the fibres are disentangled and pulled out so that they form a long uniform continuous sheet or film. From the second carding engine the thin sheet, ingeniously divided up into uniform strips, passes to the condenser, on which the strips, by passing through a smooth ring and by the action of a series of small rollers, are gradually rolled or *condensed* into a round, soft, untwisted cylindrical cord or sliver technically called a 'slubbing.' Each sliver as it is delivered from the condenser is wound on a large bobbin or spool, and in this form it is ready for spinning on the self-acting mule. In the *spinning* of woollen yarn, the point of distinguishing importance is to produce yarn as soft, woolly, and open in texture as possible, so that in finishing a nap or pile may be easily raised on its surface. The yarn is therefore only lightly spun, and it has no great cohesion. The operation of spinning is one of great nicety, and demands the most perfect and delicate machinery. In a single mule as many as 200 separate bobbins of slubbing are being spun into perfectly level, equal, and uniform yarn at the same instant, and the action of the machine draws out the slivers to the requisite degree of attenuation, and in drawing them gives that amount of twist necessary to keep the slivers from breaking, but not too much to prevent their further drawing out. Finally, the spinning mule has to give the same amount of twist to the yarn throughout, and to wind the spun yarn on the mule cops. The complexity of the machinery and adjustments used in the spinning, and indeed in all the other processes alluded to, is such as renders it impossible to attempt to convey any intelligible idea of their action within any moderate compass. The *weaving* of woollen cloth is attended with some difficulty on account of the soft and ill-compacted condition in which the yarn is purposely left, and the goods as taken from the loom present a rough and uneven appearance. After being taken out of the loom the cloth is washed to free it from oil, weaver's dressing, and other impurities which may have attached to it. The washing is done in a mixture of urine, dung, blood, and salt, and afterwards in soap-and-water. Next in the *fulling* stocks the cloth is subjected to a beating from the heavy hammer of the apparatus while abundantly supplied with soap-and-water. A further felting is communicated in the *milling machine*, in which the cloth is

further treated with a soapy solution and subjected to pressure. At this stage the cloth should have become thick, uniform, and leathery in appearance. It is again washed and stretched or *tented* equally in every direction, and while so extended it is dried either slowly or by the application of heated air. The nap or pile is now raised by passing the cloth in every direction over a frame filled with teazles, the thistle-like flower-heads of a plant *Dipsacus fullonum*. The teazles have strong elastic recurved spines which entangle themselves in the woolly surface and so raise from the now well-felted mass a velvety pile. Afterwards the pile is cut to a uniform length by a shearing machine; it is laid or made to slope in one direction by a dressing machine, after which it is hot pressed. *Lustering* or *decatting* finishes the numerous processes. It consists of wrapping the fabric smoothly and tightly on an iron cylinder and subjecting it to several immersions for a period of six or eight hours at a time in water heated to about 185° F. Finally the cloth is dried, pressed, and folded into pieces.

Worsted yarn is, as already indicated, made from long-staple wool which undergoes a combing process designed to stretch the fibres and lay them parallel to each other. The wool, in a damp state in order to prevent the tendency of the material to curl, is first fed into a series of 'preparing gill-boxes' provided with steel combs (gills) which separate and straighten the fibres. The gills of each succeeding box have finer and closer teeth than those immediately preceding, and from the last box the wool is delivered in the form of a continuous sliver. Twenty such slivers are placed together and introduced into the combing-machine, known to the trade as 'Lister's Nipping Machine.' This machine, which was patented in 1851 by Mr. S. C. Lister of Bradford, is a triumph of mechanical art, and to it is due in a great measure the extraordinary, rapid, and substantial development of the English worsted industry. It has entirely superseded the former manual operation of combing, which was not only laborious but much less productive and efficient than machine-combing. In the combing-machine the wool is fed between a pair of rollers into a series of 'screw-gills,' through which it is drawn in detached tufts by nipping jaws. The tufts are then carried by a 'porter comb' and deposited on a large circular rotating comb, and through its teeth they are drawn by a roller arrangement and delivered as a continuous sliver, called *top*. The fibres are thus laid parallel to each other, and all short portions of wool, technically termed *noils*, not fitted for making worsted yarn are separated. The top is then passed through 'finishing gill-boxes,' which condense it and prepare it for the drawing-frame. This machine consists of several pairs of rollers, and between them the sliver is repeatedly drawn with the object of uniformly extending it. Roving follows and still further attenuates the sliver, which is now ready for being spun into yarn in the throstle-frame, provided with spindles and flyers for long wool, and spindles and caps for short wool. Some varieties of worsted goods are composed of short fibres, which cannot be combed in the Lister machine, and for which an ingenious machine, invented and patented in 1853 by Mr. Noble, is employed. Before being fed into the Noble machine the fibres are carded in a carding-engine adapted for the worsted trade, and the oil imparted to them in the process is removed by washing. Worsted yarn is put up in hanks or skeins of 560 yards, and its relative tenuity is indicated by a number which gives the count per pound. Thus, '36s' yarn signifies that in 1 lb. there are 36 hanks of 560 yards each, '24s' yarn gives 24 hanks to the lb., and so on.

In the year 1871, when the wool industry was approaching its zenith in the United Kingdom, there were then in all 1829 woollen factories, having 2,727,017 spindles and 50,826 power-looms, giving employment to 64,039 males and 63,897 females, in all 127,936 persons. In the worsted trade there were 630 mills, 2,131,452 spindles, 64,454 power-looms, and the persons employed numbered 126,589, of whom 49,004 were males and 77,585 females. The following is a statement of the value of the exports of W. and W. M. during the past three years, and the figures, it will be seen, indicate that the trade during that period has been seriously declining, but more in value than in actual amount.

	1878.	1877.	1876.
Woollen Cloth, Coatings, &c. . .	£6,264,023	£6,599,717	£6,541,410
Worsted Stuffs	7,438,719	7,680,571	[illegible],141,605
Carpets	840,077	847,464	911,873
Other Articles	2,180,190	2,106,944	2,098,590

The woollen manufacture of the United States rose from $4,413,068 in 1820 to $217,668,826 in 1870, and in 1876 was estimated at $208,118,875; while the import of manufactured wool has steadily decreased from 70,896,713 in the year ending June 30, 1873, to $33,087,062 in that ending June 30, 1878. As the imports are reckoned at gold value, and without duty, their value is about double the sum stated, so that over two-thirds of the woollens in the United States markets is of native manufacture. The growth of the manufacture has increased the production of raw wool to 207 million lbs. in 1878 (in 1876, 195 million lbs., against 44,642,836 lbs. imported). The chief seats of the W. M. in the United States are Pennsylvania, New York, Connecticut, and Rhode Island, though most of the States have some manufactures of this kind.

Wooll'ett, William, an English engraver, was born at Maidstone, 27th August 1735. After an apprenticeship to John Tinney, an obscure London engraver, he adopted a style of his own, combining in a single plate the use of aquafortis, the burin, and the dry needle. His landscapes procured him a high reputation, and are remarkable for their realistic treatment of rocks, water, and foliage. Nine English landscapes after Richard Wilson have still a high artistic value. Other notable works are the engravings of Benjamin West's 'Death of Wolfe' and 'The Battle of La Hogue.' W. was long engraver to George III., and after his death, which took place in London, 23d May 1785, a monument was erected to him in Westminster Abbey.

Wool'ner, Thomas, R.A., an eminent English sculptor, was born at Hadleigh, in Suffolk, 17th December 1825 and educated in Ipswich. At the age of thirteen he entered the studio of William Behnes, under whom he worked for six years and became a skilful draughtsman. W.'s first efforts showed a fine imagination and a cultured intellect. He drew his inspiration from the high sources of poetry and history. In 1843 he exhibited at the Royal Academy 'Eleanor Sucking the Poison from Prince Edward's Wound,' and about the same time a life-size group, 'The Death of Boadicea,' the latter of which was hailed as the promise of a great career in ideal sculpture. These works were followed by figures of 'Puck,' 'Titania with her Indian Boy,' 'Eros and Euphrosyne', and 'The Rainbow' (1848). In 1850 he joined Millais, Holman Hunt, and D. G. Rossetti in establishing the Pre-Raphaelite magazine called *The Germ*, to which he contributed some poems which were afterwards gathered, with additions, into a volume entitled *My Beautiful Lady* (1863; 3d ed. 1866). In 1854 he visited Australia, where he remained for two years, and executed some fine medallions. On his return to England he produced a life-size statue of Lord Bacon for the new museum at Oxford. Among W.'s subsequent works may be mentioned his statues of Prince Albert for Oxford, Lord Macaulay for Trinity College, Cambridge, William III. for the Houses of Parliament, Sir Bartle Frere for Bombay, Dr. Whewell for Cambridge, Lord Lawrence for Calcutta, Lord Palmerston for Palace Yard; busts of Tennyson, Carlyle, Newman, Darwin, Cobden, Dickens, Kingsley, Gladstone, Lushington (University of Glasgow), Huxley, and other distinguished men. But he has not abandoned his early idealism. He is still the first of England's poets in marble. 'Elaine with the Shield of Sir Lancelot,' 'Ophelia,' 'Guinevere,' and 'Achilles and Pallas Shouting from the Trenches' (1876), show the same high aim as the earlier products of his chisel. In 1878 W. completed a colossal statue in bronze of Captain Cook for the Government of New S. Wales, which has been erected in Sydney. In 1874 he was elected an R.A., and in 1877 was appointed Professor of Sculpture in the Royal Academy.

Wool'sack, a large cushion of wool covered with red cloth forming the seat of the Lord Chancellor of England in the House of Lords. It was first introduced in the reign of Queen Elizabeth to commemorate an Act forbidding the exportation of wool, then the staple industry of the country. The term is often used colloquially to designate the office of Lord Chancellor.

Wool'sey, Theodore Dwight, D.D., LL.D., born in New York, 31st October 1801, graduated in 1820 at Yale College, where, after studying theology at Princeton, he was a tutor (1823–25). Licensed to preach in the latter year, he studied Greek in Germany (1827–30), became Greek professor at Yale College (1831), and was its president (1847–71). He still (1879) resides at Newhaven, lecturing occasionally in the law school,

and often preaching in the college chapel. A master of political science, a brilliant scholar, and a profound and catholic theologian, W. has edited four Greek plays (1833-37) and Plato's *Gorgias* (1842), and has published many sermons and discourses; but his fame is principally based on his *Introduction to the Study of International Law* (1860; 5th ed. 1879) and *Political Science, or the State Theoretically and Practically Considered* (1878). He has also written *An Essay on Divorce and Divorce Legislation* (1869), in 1874 re-edited Prof. Lieber's *Civil Liberty and Self-Government* and *Manual of Political Ethics*, and is now chairman of the American branch of the committee for the revision of the New Testament.

Wool'ston, Thomas, one of the English 'deistical' writers, was born at Northampton, 1669, studied at Sidney Sussex College, Cambridge, where he obtained a fellowship (from which he was afterwards removed), entered the Church, and spent his life in polemical warfare. He was finally fined £100 and sentenced to a year's imprisonment for the 'blasphemous' nature of his *Discourses;* and as he refused to make submission to the powers temporal and spiritual, he lay in prison till his death, 27th January 1731. W.'s chief writings are *The Old Apology for the Truth of the Christian Religion against the Jews and Gentiles Revived* (1705), *Moderator between an Infidel and an Apostate* (1725), *Discourses on the Miracles of our Saviour* (1727-30). This last work excited a profound sensation. It was answered by Lardner, Pearce, Sherlock, Smalbroke, Stevenson, and many others. Its general argument was simply this: the miracles in the Bible are incredible as they stand; those who wrote the evangelical narratives never meant that they should be taken literally; to do so amounts to blasphemy; they are *allegories*, and it is only when looked at in this light that we catch their true meaning. W. was a man of learning and ability, but the many strange vagaries of his life and in his writings force us to the conclusion that he was partially insane. See his *Life, with an Impartial Account of his Writings* (1733); also Lechler's *Geschichte des Englischen Deismus* (Stuttg. 1841), and Leslie Stephen's *History of English Thought in the 18th C.* (2 vols. Lond. 1876).

Wool'wich, a town of Kent on the southern bank of the Thames, 10¾ miles E. of London by rail. The garrison where every artillery officer or recruit must learn his art, it has few buildings of interest beyond such military establishments as the Artillery, Marine, and Sappers and Miners' Barracks, the Ordnance Hospital, the Rotunda or military museum, a Soldiers' Home (1876), and on the western slope of Shooter's Hill the Herbert Military Hospital (1865) for 700 patients. The Royal Military Academy (q. v.), partly destroyed by fire in 1873, has been restored, and since 1876 £20,000 has been expended in increasing its accommodation. From W. Dockyard, with a river frontage of 3680 feet, was launched the *Henrye Grace de Dieu* (1512), but it was closed in 1869, and three years later handed over to the military department. The famous Arsenal, however, transferred from Moorfields to the E. of W. about 1720, was never so busy as now. Four miles in circumference, it is divided into the carriage, gun factory, laboratory, saddlery, and ordnance departments. The first supplies every species of carriage, slide, and platform for naval and military guns of the heaviest calibre, besides sponges, rammers, military waggons, ammunition carts, boat pontoons, &c. Its expenditure in 1876-77 was £72,826 on materials and £70,531 in wages, exclusive of £11,992 for alterations and repairs. During 1873-76 the gun factory turned out no fewer than 2422 heavy guns, among them the famous 80-ton (1875-76), which, with a charge of 425 lbs. powder, possesses a striking force of 30,168 foot-tons. In 1876-77, 542 pieces of ordnance were produced, viz. 44 38-tons, 5 25-tons, 14 18-tons, 217 64-pounders, &c. The cost of materials was £172,664, wages amounting to £58,917, indirect expenditure to £26,127. There were further 522 guns and howitzers sighted and completed after proof, and many appliances manufactured, at a cost of £12,470; and £23,722 more was spent upon miscellaneous services. The laboratory in 1876-77 produced 65,773,930 cartridges for small-arms, and for heavy guns and other ordnance 211,064, besides 87,282 fuzes, 10,637 rockets, 231,578 shells, 222,139 heavy shot, &c., at a cost for materials of £210,280, for wages of £176,053. The saddlery department made 1596 saddles and 3322 saddle-trees; and lastly, the ordnance department comprises a gigantic armoury. W. publishes three weekly papers, and had a pop. (1871) of 35,557, including 4110 military.

Woonsock'et, a township in Rhode Island, U.S., on the Blackstone River, 37 miles S.W. of Boston by rail. It consists of a cluster of villages, which have become, from the great available water-power, active seats of manufacture. It has 9 churches, a high school, and 8 other schools, the Harris Institute with a free library of 7000 vols., 2 daily, a bi-weekly, and 2 weekly newspapers. The principal manufactures, in the production of which $6,000,000 of the $10,000,000 town valuation are invested, are woollens, cottons, india-rubber articles, machinery, and cast-iron fabrics. Pop. (1870) 11,527.

Woo'rali Poison, now generally called *curara*, obtained from the *Strychnos toxifera*, is used by the S. American Indians as an arrow poison. An alcoholic extract, called curara or Curarin (q. v.), is obtained from the crude W., which is in commerce a black-brown resinous mass, soluble in water, but slightly so in alcohol. The alcoholic extract, obtained by Roulin and Boussingault in 1828, was a solid transparent mass, of an excessively bitter taste, and possessed all the virulence of the W. P. The W. P. contains no strychnine, but belongs to the narcotic rather than to the tetanic poisons. It is extremely virulent and rapid in its action, so much so that a large animal may be killed by a poisoned arrow in five minutes, and it may retain all its properties for an indefinite length of time if kept dry.

The physiological properties of the W. P. have been investigated by numerous experimenters, such as Virchow, Münter, Bernard, Pelouze, Vulpian, and Kölliker, the last arriving at the following conclusions in 1857:—(1) That the W. P. causes death very rapidly when injected into the blood, or inserted into a wound; and that when introduced by way of the mucous membrane, its effects are slow, and require a large dose for their production; when applied to the skin of frogs it is inoperative. (2) It acts through the blood, and destroys the excitability of the motor nerves, while the sensory nerves are hardly at all affected. (3) When artificial respiration is carried on in animals under its influence, many of the secretions are increased owing to the paralysis of the vascular nerves, and the consequent dilatation of the vessels. (4) That in mammals the poison causes death by the paralysis of the respiratory nerves and suppression of the respiration, which brings on convulsions as a collateral effect.

There are two varieties, called Corroval and Vao, whose properties have been investigated by Weir, Mitchell, and Hammond. From a large number of experiments on living birds, mice, cats, frogs, and alligators, they find (1) That corroval differs essentially from any variety of W. hitherto described in its physiological results. (2) That it acts primarily on the heart through the medium of the blood, producing an arrest of the heart's action. (3) That the annihilation of voluntary and reflex motion is a secondary result of its action, depending primarily on the cessation of the heart's action. (4) That it acts upon the nerves from the surface to the centre, and abolishes both the sensory and the motor functions. (5) That it destroys muscular irritability. (6) That it paralyses the sympathetic nerve, this being one of its primary effects. (7) That it is absorbed both from the intestinal canal and skin of frogs; and (8) that its poisonous effects are due to an alkaloid hitherto undescribed. They consider that vao is only a weaker variety of corroval, and that it is quite distinct from the ordinary W.

W. or *curara* has been used in medicine in cases of hydrophobia and chorea; and discs, for use in hypodermic injection, have been prepared by Messrs Savory and Moore of London. See Hammond's *Physiological Memoirs* (1863).

Wootz, a kind of steel manufactured in India by melting malleable iron in crucibles in contact with carbon. This is the most ancient of all methods for preparing steel.

Worce'ster, a city of Worcestershire, England—and itself also a county—on the Severn, 22 miles S.W. of Birmingham by rail. It is a handsome town, mostly of red brick. The chief building is the Cathedral of St. Mary, built of red sandstone in the form of a double cross, and measuring 425 feet in length, 145 feet in width, and 193 in height. The predominant styles are Early English and Decorated. The cathedral, first erected (983), was rebuilt by Bishop Wulfstan (1084), and again (1281). Many alterations have since been made, and it has lately been elabo-

rately 'restored' at a cost of more than £100,000. It has a good tower, with a clock and carillon of twelve bells, and contains the tomb of King John and of Prince Arthur, eldest son of Henry VII. In September 1878, after an interval of six years, the 155th musical festival of the Three Choirs (of Worcester, Hereford, and Gloucester) was held in W. Cathedral. The other principal churches of W. are St. Helen's, St. Andrew's, St. Alban's, St. Martin's, all recently renovated; St. Nicholas's, entirely repaired in 1867; and Holy Trinity, erected in 1867. Other churches are St. Mary Magdalene (1876), and St. Margaret's Church (1874). Baptists, Methodists, Congregationalists, and Presbyterians have also several places of worship. W. has a guildhall, a grammar-school, hop-market, and elegant banks. A new fruit-market was opened in 1874. The theatre, destroyed by fire 24th November 1877, was rebuilt in 1878. Ruins of the castle and monastery of W. lie a short way S. of the cathedral. The grammar school and the cathedral school have a high reputation. Glove-making has long been the staple industry of W., and affords employment to over 5000 hands. The porcelain made here is also very famous for its delicacy and beauty of design. Iron-foundries have existed from time immemorial, and tanning and rope-making are carried on. Hops are extensively grown in the neighbourhood. The trade is chiefly in coal, corn, and malt. The town sends two members to Parliament. Pop. (1871) 38,116. W., which dates from prehistoric times, was successively a British fort, a Roman camp, an English stronghold, and a bishop's see (from 680). Destroyed by the Danes, it was rebuilt by Ethelred, sacked by Hardicanute (1041), and frequently by the Welsh during the following two centuries. Later on, civil commotions retarded its progress. A new charter was granted by James I. in 1622, and W. espoused the royal cause throughout the great rebellion; here Cromwell achieved his 'crowning mercy,' 3d September 1651. For its constant fidelity to the royal cause, W. received from Charles the motto still on the city arms, '*Civitas in bello et in pace fidelis*.' See the *Origin and Progress of the Meetings of the Three Choirs of Gloucester, W., and Hereford, and of the Charity connected with it*, by Rev. Daniel Lysons, M.A., F.R.S., F.S.A., continued by J. Amott, organist of Gloucester Cathedral, and E. Rimbault, LL.D.

Worce'ster, a city of Massachusetts, U.S., 60 miles W. of Boston by rail. It has 22 churches (10 Congregational, 7 Methodist, 5 Roman Catholic), a State normal school, and three academies, the library (70,000 volumes) of the American Antiquarian Society, a free public library (whose reference department was consulted by 22,833 persons in 1877, and which then had an endowment fund of $35,000), Institute of Industrial Science, hospital, lunatic asylum, large mechanics' hall, and 3 daily papers. There are 11 banks, 5 insurance companies, and 2 fine parks. By the census (1875) it appears that the district of W. has 136 boot and shoe factories, 44 clothing factories, 64 furniture-works, 95 lumber-works, 88 machinery-works, 63 woollen manufactories, 49 flour-mills, 44 clothing works, &c. There are also iron-works, paper-mills, &c. These employ upwards of 35,000 hands. Pop. (1876) 50,792. Settled in 1675, it suffered frequently from the Indians—especially Philip of Pokaoket—till 1713. Mr. Isaiah Thomas, who read here the Declaration of Independence, started the first printing-press and first paper here, 3d May 1775. W. has since grown rapidly, the valuation having increased from $22,599,850 in 1866 to $48,219,397 in 1876.

Worce'ster Coll'ege, Oxford, was founded in 1714, out of the older Gloucester Hall, by Sir Thomas Cookes of Bentley, Worcestershire, Bart., for a provost, six fellows, and six scholars. At present there are fourteen fellowships, sixteen scholarships (of about £75 for five years), and twelve exhibitions. Of the fellows four, of the scholars five, must be sons of clergymen, needing support at the universities, and six of the remaining scholarships are for scholars of Bromsgrove School. W. C. presents to ten livings, and in 1878 had 94 undergraduates, 213 members of Convocation, and 367 members on the books.

Worce'ster, Edward Somerset, Marquis of, one of the early inventors who utilised steam as a motive power, was born in 1601. As Earl of Glamorgan he was despatched to Ireland in 1645, on a secret mission, by Charles I., with the object of treating with the Catholics and raising troops for the king's service. The secret was discovered, however, and only the king's influence saved him from imprisonment. The next year he succeeded to his father's title, and in 1648 went to France as a voluntary exile. On his return in 1652 he was imprisoned in the Tower for three years, and thereafter he devoted himself wholly to the mechanical inventions which have procured him his fame. In 1663 he published a work entitled *A Century of Inventions*, in which he describes his ingenious devices for raising water through the agency of steam. W. died April 3, 1663. His *Century of Inventions*, with a commentary by Henry Dircks and a biography, was published at London in 1865.

Worce'ster, Florence of. See FLORENCE OF WORCESTER.

Worce'stershire, a midland county of England N. of Gloucester and E. of Hereford. Area, 472,453 acres; pop. (1871) 338,387. The surface is a broad undulating plain broken in the N.E. by hills of moderate elevation, and in the S.W. by the Malverns, the highest summits in the country. Red sandstone, lias, and oolites are the prevalent rocks. The soil is always excellent, and abundant water supply accessible. Scarcely 20,000 acres are yet waste. In 1878, 116,884 acres were under corn crops (62,488 wheat), 30,229 under green crops, 34,072 under clover, hay, &c., 195,294 under permanent pasture, 2474 under hops, 16,972 bare fallow. W. is famous for its pear orchards and its 'perry.' There were (1878) in the county 19,569 horses, 55,344 cattle, 215,921 sheep, 43,523 pigs. W. lies almost entirely in the basin of the Severn, which receives the Teme on its right and the Salwarp and Avon on its left. In the N. several important canals—chief among which is the Worcester and Birmingham—connect the Severn Basin with those of the Trent and Mersey. The mining of iron and coal forms a most important industry. The chief towns are Worcester, Kidderminster, Stourbridge, Droitwich, Evesham, and Upton. W. returns four members to Parliament, and the constituency numbers 18,166. The gross rental (1877) was £2,004,440, the poor rate (1878) £164,780, and the number of paupers (1878) 9636.

Worde, Wynkyn de, one of the earliest English printers, was a native of Lorraine. Whether he was with Caxton at Bruges is open to question, but he was certainly for many years in the famous office at Westminster, and succeeded to the business on his master's death. About 1500 he removed to the city, and from 1502 till his death in 1534 he had his office at the sign of the 'Sun' in Fleet Street. He was appointed king's printer, enjoyed the patronage of Margaret, the mother of Henry VII., and attained a good position as a citizen of London. Though less scholarly than Caxton, W. did excellent service to his art. He was his own typefounder, and not only did he set the fashion of employing Roman letters as we now use italics, but he was the first to introduce Greek types into England, and in some of his works he inserted Hebrew and Arabic characters cut in wood. Of the four hundred and odd books which proceeded from his press it is enough to mention *Bartholomæus de Propriatatibus Rerum* (without place or date, but about 1495), which was the first book printed on English paper, and ranks as altogether his finest production; *Scala Perfectionis* (1493), *Bonaventuras Speculum Vitæ Christi* (1494), Trevisa's *Polichronicon* (1495). See Blades, *Life of Caxton*; Bullen. *Caxton Celebration Catalogue* (Lond. 1877).

Words'worth, William, son of John W., attorney and agent for Lord Lonsdale, was born at Cockermouth, April 7, 1770. Left an orphan at the age of fourteen, after preliminary education in his native town he attended a school at Hawkshead in Lancashire. In his eighteenth year he proceeded to St. John's College, Cambridge; but an academical career was not what he sought or achieved. After a pedestrian tour on the Continent with a fellow-student named Jones, he took his degree in 1791. In the autumn of that year he again visited France, where, amid the revolutionary ferment, he involved himself with the Girondists, and circumstances which obliged his return to England alone saved him from the guillotine, as he himself confessed. In 1793 he published *Descriptive Sketches* and *An Evening Walk*. 'Seldom, if ever,' says Coleridge, 'was the emergence of an original poetic genius above the literary horizon more evidently announced.' This laudation must refer solely to the *Descriptive Sketches*, memorials of his first tour abroad. Notwithstanding counsel that he should enter the Church, he

projected a periodical to be called the *Philanthropist*, and was looking out for newspaper employment when a legacy of £900 was left to him by his friend Raisley Calvert. Probably no such sum ever before produced so rich a poetical return. 'Upon the interest of the £900,' W. writes, '£400 being laid out in annuity, with £200 deducted from the principal, £100 a legacy to my sister, and £100 more which the *Lyrical Ballads* brought me, my sister and I contrived to live seven years, nearly eight.' There also came to the poet and his sister about £1800 each, arrears due by Lord Lonsdale; and in fairly comfortable circumstances they established themselves at Racedown, in Dorsetshire. There W. wrote a play called *The Borderers* (published 1842), only to demonstrate his utter lack of dramatic power. There, also, he met Coleridge; and the resulting friendship led him to become Coleridge's neighbour at the village of Alfoxden, Somersetshire. In 1797 the pair made a pedestrian trip, the first fruits of which was *Lyrical Ballads* (1798). This collection, beginning with the Ancient Mariner and ending with the exquisite lines on Tintern Abbey, was mainly an experiment towards simplicity in poetical diction. But the public thought the greater part of the diction much too simple, and Cottle, the publisher, counted the volume a dead loss. In 1799 W. took up his abode at Grasmere after a sojourn in Germany, and in the following year appeared a second volume of *Lyrical Ballads*, accompanied by an essay on the principles of poetry. In 1802 W. married Mary Hutchinson of Penrith, in praise of whom, three years after marriage, he wrote the beautiful poem, 'She was a phantom of delight.' In 1813 he removed to Rydal Mount, Westmoreland, for which county Lord Lonsdale made him distributor of stamps. This office brought him £500 a year, and its duties were performed by deputy. Next year was published *The Excursion*, a long poem, diffuse in style, lacking plan, and altogether too much like a dissertation, yet abounding in more subtle descriptive and meditative poetry than English literature had yet seen. W.'s innovations in style, many of them ludicrous affectations, had exposed him to the merciless mockery of Jeffrey and other critics, and obscured the rare nobility of his thought. Even in the *Poems* published in 1807 these mannerisms were frequent. But such as remained in *The Excursion* scarcely blemished the greatness of the work; and its author had to be acknowledged master of a new and splendid school. In 1815 W. increased his reputation by the tale of *The White Doe of Rylstone*, but unfortunately the scoffers could make merry over his next production, *Peter Bell* (1819), wherein are described the virtues and travels of 'a solitary ass.' The foundation of a great reputation had been laid, however, and W.'s history up to 1839 is one of new editions and increasing triumph. In that year Oxford conferred on him the degree of D.C.L.; in 1842 he retired from his office in favour of his second son, with a pension of £300; and in 1843 he succeeded his friend Southey as laureate. He died 23d April 1850, St. George's Day, and the anniversary of Shakespeare's death. The autobiographical *Prelude*, written so long ago as 1805, was published posthumously in 1850. W. is among the first half-dozen English poets, and is the greatest since Milton. His early republican sentiments were inflamed by the wondrous spectacle of the French Revolution, not even the horrors of which abated the ardour of his enthusiasm. At last, however, the profligacy and irreligion of the Revolution, followed by the insolent despotism of Napoleon, hardened him into a Tory. As Scott turned in disgust from his own age to the illusions of romance, W. turned to the sanctities of Nature. His dreams of perfect human brotherhood were at an end, but his imagination sought ideal communion with the pure loveliness and solemn grandeur of the external universe. The school of poets reigning when W. appeared were blind to nature, or looked on it as a dull, dead painting. W. set himself to study an 'infinite variety of natural appearances that had been unnoticed by the poets of any age or country.' He recognised a soul in nature, and rendered homage to her personality; and it is as Nature's high priest that he stands alone among all other poets. In pure originality, *i.e.*, in absolute self-dependence of genius, he has no superior in any age, and no compeer in his own. Even Keats and Shelley with all their unique and splendid powers of imagination do not disdain to learn from him; but he learns from no one. His thoughts have a divine freshness and beauty, as if nature in some supremely gracious mood had whispered to his soul her inmost secrets, and gifted him with a novel magic in uttering them. Though not habitually melodious in his verse, there are poems and stanzas and lines of his which no English poet, not even Shelley or Coleridge, has surpassed. The Ode entitled *Intimations of Immortality from Recollections of Early Childhood* is a miracle of various music; and in its rich alternations of description, sentiment, and reflection, from the radiant and gleeful opening to the profoundly tender and pensive close, marks the highest reach of poetic inspiration in the 19th c. W.'s serene life was in harmony with his noble teaching, and even his two great faults reflect on his contemporaries as much as on himself; for his parsimony and egotism resulted from neglect and contempt that have reduced less earnest men to want and despair. His fine Prose Essays, edited by Grosart, were published in 3 vols. 1875. The best edition of W.'s *Poems* is that of Moxon (6 vols. 1874). Interesting glimpses of the poet are given in his sister's *Diary of a Tour in the Highlands* (1874). Memoirs of him have been written by his nephew Christopher W. (1851), and by Paxton Hood (1856). Many sketches of W. occur in the writings of his contemporaries, as in the reminiscences of Rogers, De Quincey, and Crabb Robinson; for definite criticism of his writings see Coleridge's *Biographia Literaria*, Jeffrey's *Essays*, Masson's *Essays* (1856); F. W. Robertson's *Lectures and Addresses* (1858); Shairp's *Essays and Studies in Poetry and Philosophy* (1868); Sir Francis Doyle's *Lectures on Poetry* (1869); and Hutton's *Essays* (1871).—**Christopher W.**, youngest brother of the poet, born at Cockermouth, June 4, 1774, after schooling at Hawkshead entered Trinity College, Cambridge, where he took his degree in 1796, and obtained a fellowship in 1798. In 1802 he published *Six Letters to Granville Sharpe on his Remarks on the Uses of the Article Definite in the Greek Testament.* Manners Sutton, Archbishop of Canterbury, thereupon appointed him his domestic chaplain, and he was presented with a rectory and the deanery of Bocking. His *Ecclesiastical Biography* (6 vols. 1810; reissue, 10 vols.) attracted the royal notice, and he became in 1814 rector of St. Mary's, Lambeth, in 1816 chaplain of the House of Commons, and in 1820 Master of Trinity College, Cambridge. His other works are *Sermons on Various Occasions* (1814), *Who Wrote Eikon Basilike?* (1824-25), *Charles I. Author of Eikon Basilike Further Proved* (1828), and *Christian Institutes* (4 vols. 1836). W. resigned his mastership in 1841, and died at his rectory of Buxted, Sussex, 1846.—**Charles W., D.C.L.**, son of Dr Christopher W., Master of Trinity, was born at Bocking, Essex, in 1806, was educated at Harrow, and entered Christ Church, Oxford. After a distinguished undergraduate career, he became B.A. in 1830. In 1829 he had been a member both of the Oxford Eight and the Oxford Eleven. He remained at the university for a year or two as tutor; in 1835 was chosen second master of Winchester College; and in 1846 accepted the wardenship of Trinity College, Glenalmond, Perthshire. This institution owes much of its success to W., who erected its chapel at a private cost of £8000. In 1852 he was made Bishop of St. Andrews, Dunkeld, and Dunblane. He is one of the New Testament Company for the Revision of the authorised version of the Bible. His chief works are *Græcæ Grammaticæ Rudimenta* (1839; now in its 16th ed.); *Christian Boyhood at a Public School* (1846); *The College of St. Mary Winton* (1848); *On Shakespeare's Knowledge and Use of the Bible* (1854); *Catachesis, or Christian Instruction* (4th ed. 1864); *A Greek Primer* (1870; 6th ed. 1879); and *The Outlines of the Christian Ministry* (1872).—**Christopher W., D.D.**, also son of Christopher W., born at Ashby, Norfolk, in 1807, after education at Winchester, entered Trinity College, Cambridge, and obtaining a fellowship there, travelled in Greece during 1832–33. The records of this tour are to be found in *Athens and Attica* (1836; 4th ed. 1869). After taking holy orders, W. became headmaster of Harrow School and public orator at Cambridge (1836), canon of Westminster (1844), and vicar of Stanford-in-the-Vale, Berkshire (1850). On February 4, 1869, he was consecrated Bishop of Lincoln; and in September of 1872 he took part in the Old Catholic Congress at Köln. His other works are:—*Ancient Writings Copied from the Walls of Pompeii* (1838); *Greece, Pictorial, Descriptive, and Historical* (1842); *The Correspondence of Richard Bentley* (1842); *Theophilus Anglicanus, or Instruction for the Young Student Concerning the Church* (1843; 10th ed. 1874); *Diary in France* (1845); *On the Canon of the Scriptures* (1848); *Lectures on the Apocalypse* (1849); *Memoirs of William W.* (1851); *St. Hippolytus and the Church of Rome* (1853); *Remarks on M. Bunsen's Work on St. Hippolytus* (1855); *Social Life at the English Universities in the*

18th C. (1874); *Sermons on the Maccabees and the Church* (1871); *Scholæ Academicæ: English Universities in the 18th C.* (1877), and *Miscellanies, Literary and Religious* (3 vols. 1879). W. has likewise published a *Theocritus* (1844), a well-known edition of the Greek Testament (4 parts, 1856–60), and *The Holy Bible, with Notes and Introductions* (2 vols. 1864 70).

Work, in physics, is defined by Clerk Maxwell as the act of producing a change of configuration in a system in opposition to a force which resists that change. For example, in raising a mass from the earth's surface, work is done in overcoming the attraction between the earth and the mass, *i.e.* in opposition to the weight of the mass, and the work done is measured by the product of this weight into the distance through which it is overcome. To do this W. a certain force must be applied, a certain transformation of Energy (q. v.) accomplished. The principle of W. done is, indeed, a particular statement of the doctrine of the conservation of energy, and was clearly enunciated, as far as it concerns pure dynamics, by Newton in the scholium to the third law of motion (see MOTION, LAWS OF). This scholium is thus paraphrased by Thomson and Tait (see their *Natural Philosophy*, vol. i. 2nd ed. 1879): 'W. done on any system of bodies has its equivalent in W. done against friction, molecular forces, or gravity, if there be no acceleration; but if there be acceleration, part of the W. is expended in overcoming the resistance to acceleration, and the additional kinetic energy developed is equivalent to the W. so spent.' Mathematically interpreted, this theorem is an explicit statement of the dynamical principle first formulated by D'Alembert in 1742, and still known by his name—a principle which enables us to write down the equations of motion for any system for which the equations of equilibrium have been investigated. Any alteration in the configuration of a material system indicates that W. is being done upon it by the forces to which it is subject. Hence, if P, Q, R, &c., be the forces acting upon a system, and if dp, dq, dr, &c., be the corresponding minute displacements produced in the first instant of time by those forces acting unconstrainedly, then, since Pdp represents the W. which would be done by P during this interval, and similarly for the others, the equation

$$Pdp + Qdq + Rdr + \&c. = 0$$

is the condition that no W. on the whole is done, and that the system is consequently in equilibrium. This is the so-called principle of *Virtual Velocities*, which Lagrange made the basis of his *Mécanique Analytique*, and is also a part statement of the conservation principle. See ENERGY, KINETICS, STATES.

Workhouse, an institution for the indoor relief of paupers. The early workhouses were to a certain extent Houses of Correction. Thus Bridewell was allotted to the City of London by Edward VI. for the correction and retention of the thriftless, vagrant, and disorderly poor. Indigence was formerly treated as penal, and the destitute and unfortunate shared the same fate as the rogue and vagabond. In the reign of Queen Elizabeth a number of workhouses were established, and some distinction was made between the two classes. The Act of 1723 (9 Geo. I. c. 7) authorised several parishes to unite in maintaining a W., which was the first step towards centralisation. The 'W. test,' by which applicants for relief were bound to enter the W. and submit to its discipline, was adopted, and was actively in force till 1815. The basis of a new system of public relief was laid by laws of 1834 and 1835. Commissioners were empowered to order a W. to be erected or hired, enlarged or altered, with the consent of the Board of Guardians elected by the parishes composing a poor-law union—each parish of the union to pay its proper proportion of costs according to the number of its poor. The administration of workhouses is now carried on under the Local Government Board.

Paupers are maintained by the parish upon which they have a claim by the laws of settlement, according to birth, parentage, marriage, residence, &c. No pauper who has been allowed to reside in a parish or union for a year is removable therefrom. Paupers are admitted to workhouses by a written order by the Board of Guardians, the relieving officer, or the master of the W. They are medically examined, cleansed, clothed in W. dress, and passed into their proper class. There is a classification of inmates according to sex, age, and physical or mental condition. Any money found on the person of an applicant is applied to the funds of the union. Inmates must set to work, leave off work, and go to bed according to the regulations. No food is allowed except the house dietary. A pauper must attend morning and evening prayers, and divine service every Sunday, but consideration is shown to his religious persuasion, and he may be visited by a minister of his own faith. Children are classified religiously according to the persuasion of their parents. Misconduct may be punished by solitary confinement and altered diet for short periods. Patients suffering from infectious diseases are usually sent for the time to public hospitals. The chief deterrent elements of the English W. discipline seem to be—(1) a diet inferior to that of the ordinary labourer, (2) constant confinement within W. walls, and (3) a task of hard work suited to age, strength, and capacity. Any adult may leave the W., unless there are medical objections, on giving reasonable notice, but cannot take away any clothes or other W. property without special permission. A chaplain, medical officer, master, matron, schoolmaster, and schoolmistresses are attached to each W. Workhouses are subject to the inspection of a visiting committee of the board of guardians. Casual wards are attached to workhouses for the relief of indigent wayfarers, called casuals in England and night-lodgers in Scotland. Casual adult males for one night in England receive lodging and 8 oz. of bread, or 6 oz. of bread and 1 pint of gruel or broth, and in return must break from 1½ to 2 cwt. of stones, and pick 1 lb. of unbeaten or 2 lbs. of beaten oakum.

Workhouses vary greatly in size. Liverpool, Manchester, and St. Pancras workhouses are among the largest in England. Some establishments, such as Poplar W., are ordinarily set apart exclusively for the able-bodied poor. There are over 600 unions in England and Wales, and on 31st December 1876, 149,853 individuals were receiving relief therein. The number on a given day is, of course, greatly less than the number receiving relief throughout the year. £1,534,224 was expended in England on indoor relief in 1876.

Workhouses are legally known as poorhouses in Scotland, in which country their regulations differ but slightly from those in England. Scottish poorhouses are regulated by the Board of Supervision, under whose approval they may be erected in any parish containing over 5000 inhabitants on a resolution of the Parochial Board. There were 62 poorhouses in Scotland in August 1877, with accommodation for 14,290 paupers. There are about 180 poor-law unions in Ireland.

Foreign Workhouses.—On the Continent outdoor relief is the rule, the helpless and homeless poor being cared for principally in the hospitals. In France it was decreed by the National Assembly in 1793 that central almhouses should be established for able-bodied beggars, but this was not carried out till 1808, when 58 departmental almshouses were opened. These institutions gradually became jails, hospitals, and asylums. After 1830 the system of departmental almshouses was revived on the principle that in future paupers should be incited to work. The Second Empire favoured central almshouses, of which in 1872 France possessed 46. They cost less than 1,000,000 francs, and supported 5470 persons. There are no indoor paupers in France, saving lunatics, the sick and infirm, and neglected children. Foundling children when possible are not maintained in hospitals, but are put out to nurse in the country. In Holland, all vagrant and able-bodied paupers are compelled to work at the three pauper colonies of Amsterdam, Middelburg, and Groningen, besides which free pauper colonies for destitute families are supported by private charity. There are 2150 almshouses, and over 50,000 paupers, in Sweden. Central workhouses and almshouses exist in every province of the German Empire. A W. was erected by Friedrich II. in Berlin in 1742 as a house of correction, and is still in existence as a place of shelter. The number of indoor poor in Prussia averages less than 50,000. Pauper children here are boarded out. In the Austrian Empire public assistance is organised on the communal or municipal basis. The system of outdoor relief, applied under strict supervision, is extending all over the world, combined with judicious indoor relief in popular communities.

United States.—In most of the United States, workhouses, or, as they are there called, almshouses, are maintained in towns and counties. There are 600 almshouses in New England, with State almshouses in Massachusetts and Rhode Island. Outside of New England the indoor poor are usually maintained in the county almshouses, lunatic asylums, and orphan homes. Each state is responsible for its own poor-laws. Among the

most celebrated almshouses in America are those on Blackwell Island, New York, that on Deer Island, near Boston, and the Philadelphia County Almshouse. The workhouse on Blackwell's Island is on the cellular system, the inmates being locked up in cells when not at work or meals. The men are employed at getting out stones, making roads, building sea-walls, &c., and at various trades; and the women at needlework and washing ten hours a day. Accounts may be kept here with paupers, charging them for maintenance and giving a fair compensation for labour, any balance to be paid over on the pauper's discharge. See article on POOR AND POOR-LAWS, and authorities there quoted; also Archbold's *Poor-Law* (13th ed. 1878), and *Parliamentary Report on Poor-Laws of certain of the United States*, by J. J. Henley (August 1877).

Work'ing Draw'ings are drawings on a scale sufficiently large to exhibit with clearness and accuracy the details of a work for the guidance of workmen, as builders, decorators, engineers, pattern-makers, &c. In some cases W. D. are made of the actual size of the object to be executed. They are generally drawn in outline, and the sections are tinted to render them the more obvious.

Work'ing Par'ty, in the army a body of soldiers told off for manual labour. When the work is necessary for military exigencies, such as the throwing up of works, clearing space for a camp, &c., no working pay is allowed; but when men are employed as artificers or labourers on permanent military works, roads, &c., they may, under the Queen's Regulations, be granted a small extra remuneration in addition to their ordinary pay.

Work'ington, a seaport of Cumberland, England, 7 miles N. of Whitehaven by rail, stands on the Derwent, a mile above its mouth. Finer than either of its two Anglican churches is a Catholic church, erected in 1876 at a cost of £10,000; and other buildings are a corn-market, assembly rooms, dispensary, &c. The harbour, improved by the construction of a breakwater (1873), was entered in 1878 by 956 vessels of 107,947 tons, and cleared by 926 of 103,224 tons, the imports amounting (1877) to £21,269; the exports (coal and iron) to £142,612 (£225,236 in 1873). Shipbuilding (12 British vessels of 10,309 tons in 1874-78), the manufacture of iron, and coal-mining are the leading industries of W., which publishes one weekly newspaper. Pop. (1871) 8413. W., by Leland described as a 'lytel prety fyscher town,' was the place where Mary Queen of Scots landed in her flight from Langsyde, May 16, 1568.

Work'shop Regula'tion Act, 1867 (30 & 31 Vict. c. 46), is an 'Act for regulating the hours of labour for children, young persons, and women employed in workshops; and for other purposes related thereto.' It extends the protective legislation of the Factory Acts to small establishments, a workshop signifying any room or place whatever, whether in the open air or under cover, in which any handicraft is carried on. Its provisions are (1) that no child under the age of eight shall be employed, (2) that no child under thirteen shall be employed for more than six and a half hours in one day, which must be between 6 A.M. and 8 P.M., (3) that no young person under eighteen or woman shall be employed more than twelve hours in one day, which must be between 5 A.M. and 9 P.M., and must embrace an intervening period of rest of one and a half hours, (4) that no child, young person, or woman shall be employed on Sunday, or after 2 on Saturday afternoon, except where not more than five persons are employed, and where retail articles are sold or repaired, and (5) that no child under eleven be employed in grinding in the metal trades, or in fustian-cutting. Every child must attend school a certain number of hours in the week. Masters in the grinding trades must take measures to protect their workmen from the inhalation of dust. The Act does not apply to bakehouses as defined by the Bakehouse Regulation Act, 1863. Penalties of not more than £3 upon occupiers of workshops, and 20s. upon parents of children, may be enforced. The inspectors and sub-inspectors of factories may enter any workshop at any time to see that the provisions of the Act are not infringed.

The W. R. A., 1871 (34 & 35 Vict. c. 19), is an Act for exempting persons professing the Jewish religion from penalties in respect of young persons and females professing the same religion working on Sundays. The Factory and Workshop Act, 1871 (34 & 35 Vict. c. 104), makes exemptions in factories and workshops in cases of trades dependent on the weather and seasons to the effect that young persons of fourteen and upwards may work fourteen hours for ninety-six days in the year, but not for more than five days in one week. By the statute of 1878 (41 Vict. c. 16) the Acts relating to factories and workshops were consolidated.

Works and Public Buildings, Board of, by the constitution of 1851 was invested with the control of public works and buildings, the management of the parks in the metropolis, besides those of Richmond, Greenwich, Bushy, Phœnix, and Holy Rood, together with the gardens at Kensington, Kew, and Hampton Court, but it was relieved of its duties in connection with the metropolis by the Metropolis Management Act of 1855 and subsequent Acts, by which a special Metropolitan Board of Works was created, to whose energy London owes its Main Drainage, the construction of the Victoria, Albert, and Chelsea embankments, and the opening up of numerous fine streets. The powers of this local Board are extensive, embracing, besides the control of streets, the gas, water, tramways, artisans' dwellings, contagious diseases (animals), slaughter-houses, explosive substances regulations, &c. It raises money not only for its own purposes, but for advances to the London School Board, the vestries, District Boards, Boards of Guardians, &c. Members are elected by the respective vestries and district boards in the metropolis. The Corporation of the City of London elect three members. For the year ending December 31, 1877 it disbursed £2,314,281. The *B. of P. W. and B.* is under the control of the Treasury, whose sanction must be obtained for all important outlays. Its members consist of a First Commissioner, who is a political officer and has a seat in the Cabinet, the Secretaries of State, and the President and Vice-President of the Board of Trade. The expenses of the department are annually voted by Parliament. In 1879 these amounted to £39,850.

Work'sop, a town in Nottinghamshire, England, on the Ryton, 146 miles N.N.W. of London by rail. From the number of mansions and parks in the neighbourhood, the district has been designated the 'Dukery'—the principal being Clumber Park, the seat of the Duke of Newcastle; W. Manor, formerly belonging to the Duke of Norfolk, now to the Duke of Newcastle; Welbeck Abbey, the seat of the Duke of Portland; and Thoresby Park, recently of the Duke of Kingston, now of Earl Manvers. The parish church is one of the finest examples of late Romanesque style in England. Other notable buildings are the town-hall and corn-exchange in the Venetian style (1854), the moot-hall, a very ancient structure, formerly used as a town-hall, the savings-bank (1843), and the mechanics' institute with a library of 2000 vols. W. manufactures Windsor chairs, has a large malt and flour trade, and is a considerable depôt of hard and soft timber for railway purposes and for the Sheffield trade. Pop. (1871) 10,409. See *W., the Dukery, and Sherwood Forest* (Worksop 1875).

Worm Fever is a popular though erroneous term sometimes applied to Typhoid or Enteric Fever (q. v.) in young children.

Worm Grass. See SPIGELIA.

Worms, an island belonging to the Russian province of Esthonia, lying between the island Dagö and the mainland. Area 34 sq. miles; pop. 1200. W. is flat in the interior. The inhabitants are of Swedish origin, and have preserved their language. Their chief occupations are tillage, fishing, piloting, cattle-rearing, and the making of goats'-milk cheese.

Worms, one of the oldest towns of Germany, in Hessen-Darmstadt, in the rich plain of the Wonnegau, ¾ mile from the left bank of the Rhine, 40 miles S.S.E. of Mainz by rail. It is irregularly built, and is still in part surrounded with its ancient walls, within the ample circuit of which, however, are many vacant spaces once covered with populous streets and fine buildings. The principal edifice in the town is the venerable cathedral (founded in the 8th c., completed and consecrated in 1101), a noble Romanesque structure with four elegant towers, two domes, and a double choir. The interior is 357 feet long, 87 feet wide (across the transepts 117 feet), and is very imposing from its grand simplicity. On the N. side of the cathedral is the site of the Bischophof or episcopal palace, the seat of the diet of April 1521. It was destroyed by the French in 1689, and again in 1794. On its massive red sandstone substructure

the Heil'sche Haus has been erected in the rich Renaissance style. Outside the town stands the Liebfrauenkirche (dating from the 15th c.), which gives its name to the *Liebfrauenmilch*, a much-esteemed wine grown in the vicinity. The finest monument in W. is that to Luther, erected from Rietschel's designs in 1868 at a cost of £17,000. The principal industries of W. are the manufacture of patent leather (employing 2000 persons), tobacco, beer, soap, and amber wares. Pop. (1875) 16,597. W. is one of the most historical towns of Germany. It was known to the Romans as *Borbetomagus*, and later as *Augusta Vangionum*, the capital of the Vangiones. It was destroyed by Attila and rebuilt by Chlodwig in 486. After the partition of the empire among the sons of Ludwig the Pious, W. became a German free-town under the protection of the Elector of the Palatinate. Already in 1255 it belonged to the Confederation of Rhenish towns, and it contained in the time of Friedrich Barbarossa 70,000 inhabitants. It was the seat of many Imperial Diets, most famous that under Karl V., which Luther made memorable to the world. In 1632 the suburbs of the town were levelled by the Swedish Colonel Haubold, and in 1689 the town itself was ruthlessly destroyed by Melac and the young Duc de Créqui under the orders of Louis XIV. In September 1792 part of it was levelled by the French under Custine, and at the Peace of Lunéville in 1801 it was given to France. The Peace of Paris in 1814 gave it back to Germany, and the Vienna Congress in 1815 to Hessen-Darmstadt. See Fuch's *Geschichte der Stadt W.* (Worms 1868).

Worms may be taken to indicate (1) the class *Annelida*, the members of which have jointed bodies, and want true articulated appendages. Examples are found in (*a*) the order *Suctoria* or *Hirudinea*, including the leeches, &c.; (*b*) the *Oligochætæ*, represented by the earthworms; (*c*) the *Tubicola*, or tube-dwellers, represented by the marine *Serpulæ* and *Sabellæ*, &c.; and (*d*) the *Errantia*, represented by the *Lob Worm*, the *Nereis*, *Eunice*, and other marine forms; (2) to such animals as the parasitic Tapeworm (*Tæniada*), the *Nematoid* W., the Thorn-headed W., and allied forms. A tapeworm differs from an ordinary worm in the compound nature of its body. Each 'joint' or *proglottis* is a complete being having a set of generative organs. By many authorities the tapeworms and their neighbours, ranked with the *Echinodermata* as the division *Scolecida*, are regarded as merely a lower branch of the Annulosa. The following particulars may serve as a succinct account of the Annelida or true W. Two classes are included in the *Arthropoda;* namely, Class 1, Gephyrea, ex. Spoon W. (*Sipunculus*). Class 2, Annelida, ex. Earthworm (*Lumbricus*). Class 1 (Gephyrea).—In this class are included the various species of spoon W. (*Sipunculoidea*), small worm-like forms, which inhabit the sand of our coasts, or seek protection in the cast-off shells of certain mollusca. They exhibit the essential annulose characteristics, the body being segmented, and the nervous system consisting of the typical ventral gangliated cord. Lateral appendages are wanting, as also are eyes and other organs of sense. A proboscis bearing the mouth, and surrounded by tentacles, is situated anteriorly, the posterior part of the body being comparatively thick and muscular. Class 2 (Annelida).—This class is as extensive as the preceding was limited. It includes the various kinds of W. The body in general is distinctly segmented, each zone or segment being furnished with locomotive appendages. A detached segment of the body of a typical annelid consists of two halves or arcs, named, from their position, the 'dorsal' and ventral arcs. From the sides of each, certain processes, termed 'parapodia' or 'foot-tubercles,' arise, and of these, four exist to each segment, two borne by each arc of the segment. The tubercles on the dorsal arc are termed, from their position, 'notopodia;' those of the ventral half, from their proximity to the nervous system, are known as 'neuropodia.' The terms 'dorsal oar' and 'ventral oar' are sometimes used synonymously with the above. Each 'oar' or 'parapodium' bears two distinct kinds of appendages, (1) bristles or 'setæ,' which form the bulk of the organ; (2) a soft tentacular filament, to which the name of 'cirrhus' is applied. These organs materially assist locomotion. The head is generally differentiated from the other segments, and in many cases is furnished with eyes, antennæ, and similar organs. The digestive system includes a mouth—provided, in some instances, with a series or jaws—a stomach, and intestine. The respiratory organs consist of skin-sacs or pouches, or of *branchiæ* or gills; whilst in the lower forms breathing is performed by the general surface of the body. The nervous system consists of the typical gangliated chain, the anterior ganglia showing a tendency to coalesce together, so as to form a rudimentary 'cerebral' mass or brain.

Worms, *as a Disease.* W. frequently inhabit the intestinal canal in children, and they often aggravate or even give rise to gastric and intestinal disorders, while the irritation which they produce is frequently propagated to the spinal cord, giving rise to convulsions or other formidable nervous symptoms. Although intestinal W. are more frequent in early life than in adult, no species of them are peculiar to infancy. The *Ascaris vermicularis*, or small thread-worm, which inhabits the rectum, is very troublesome from the local irritation which it excites. The long thread-worm, *Trichocephalus dispar*, inhabits the upper end of the large intestines, and frequently co-exists with ascarides in the rectum. The *Ascarides lumbricoides*, or round-worm, is much less common in this country than the small thread-worm. It dwells in the small intestines, and sometimes passes into the stomach, whence it is rejected by vomiting. The tape-worm—of which there are two varieties, the *Tænia solium* and *Tænia lata*—is seldom met with in children under seven years of age.

The small thread W. produce a most distressing itching and irritation about the anus, which is always most troublesome at night and frequently prevents the child from getting sleep. Sometimes they give rise to troublesome diarrhœa and tenesmus, or straining at stool, and in female children they may pass into the vagina and cause Leucorrhœa (q. v.). Round-W. very frequently give no evidence of their existence, the expulsion of one by stool or by vomiting being often the first indication of their presence. It is commonly believed that children infested with lumbrici have inordinate appetites, as the W. subsist on the contents of the alimentary canal, and not on the juices of the lining structures themselves, as in the case of tape-W. The irritation caused by the W. often produces troublesome diarrhœa, but this condition favours their expulsion. It occasionally happens that round W. pass from the stomach into the œsophagus, and from thence into the nostrils or larynx, and cause death. The irritation caused by W. frequently gives rise to violent convulsions and other cerebral symptoms. The symptoms of tænia or tapeworm are common to it and to the lumbrici; but the tape-worm is apt to produce a more decided impairment of the general health, and its symptoms are usually more persistent.

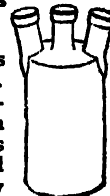
The different varieties of W. require different modes of treatment. Thread W. are scarcely affected by internal remedies taken by the stomach; but their destruction and expulsion is certain by the administration of medicated enemata. For this purpose lime-water enemata may be given; or six ounces of lime-water and two drachms of the tincture of the sesquichloride of iron. Küchenmeister, the greatest authority on helminthology, also recommends santonin in an enema in the proportion of from four to eight grains. For the expulsion of the round W. santonin in small doses is by far the safest and most efficacious remedy. For a patient six years old, two or three grains may be given at night followed by a full dose of castor-oil in the morning, and this should be repeated two or three times in succession. Santonin has no effect upon tapeworm; for the cure of which, as well as lumbrici, cusso, oil of male fern, or kamella, are the most effectual remedies.

Worm Seed is the unexpanded flower-heads of *Artemisia maritima*, var. *Stechmanniana.*

Worm'wood (*Artemisia Absinthium*), a strong-growing aromatic perennial, covered with a silky pubescence, and native over a wide range in the N. hemisphere. It is found wild in some parts of Britain, but is more commonly seen as a cottage-garden plant, having been formerly much employed as a vermifuge and a tonic. Its active properties depend on a volatile oil peculiar to the species, a bitter principle called absinthine, and absinthic acid.

Wor'num, Ralph Nicholson, an English art-critic and historian, was born at Thornton, Northumberland, December 29, 1812, and studied at University College, London. During 1834-39 he carefully examined the art-galleries of the Continent,

and on his return to England contributed articles on his favourite subject to the *Penny Cyclopædia*, and to Dr. Smith's *Dictionary of Greek and Roman Antiquities.* In 1845 he was appointed to draw up the official catalogue of the National Gallery, became art-lecturer to the Government Schools of Design (1848), librarian to these schools (1852), and Keeper and Secretary of the National Gallery (1855). He died at Hampstead, December 15, 1877. W. wrote *A Sketch of the History of Painting* (1846; 4th ed. 1861), *Analysis of Ornament* (1856), *The Epochs of Painting, a Biographical and Critical Essay on Painting and Painters of all Times* (1864), and a *Life of Holbein* (1867). He also edited Walpole's *Anecdotes of Painting* (1839; new ed. 1862), and the *Lectures on Painting* (1848) by the Royal Academicians Barry, Fuseli, and Opie, besides publishing many special essays, reports, catalogues, &c.



Worsaae', Jens Jakob Asmussen, the eminent archæologist, was born at Veile in Jutland, Denmark, 14th March 1821. He studied at Copenhagen first theology, then law, and from 1838 to 1843 was assistant at the Royal Museum for Northern Antiquities. After several scientific tours in Denmark, Sweden, and Norway, he visited Germany in 1845, and published at Copenhagen in 1846 *Die Nationale Alterthumskunde in Deutschland.* In 1846–52 he investigated the traces of the Northmen in England, Scotland, Ireland, France, and Italy. Appointed (1847) Government Inspector of Antiquities in the Danish State, W., along with Thomsen, was charged (1849) with the formation of a special commission for the preservation of Danish antiquities, and in 1865 he was appointed director of the Royal Museum and of the collection in Rosenborg Castle. From July 1874 to June 1875 he was Church and Education Minister under Fonnesbech. W. has also written *Danmarks Oldtid* (Copenh. 1843; Eng. trans. 1858); *Blekingske Mindesmærker fra Hedenold* (1846); *Danevirke* (1848); *Om Danmarks Tidligste Bebyggelse* (1851); *Minder om de Danske og Nordmandene i England, Scotland og Irland* (1852; Eng. trans. Lond. 1852), *Afbildinger fra det Kongelige Museum for Nordiske Oldsager* (1854), *Den Danske Erobring af England og Normandiet* (1863), *Den jydske Halvo og den Fortidsminder* (1864), and *Om Slesvigs eller Sonderjallareds Oldtidsminder* (1865), besides numerous articles in Scandinavian periodicals.

Wors'ted is a variety of woollen yarn made from long wool and prepared for spinning by a process known as combing. See WOOLLEN and WORSTED MANUFACTURES.

Worth'ing, a well-known watering-place in Sussex, on the coast of the English Channel, 10½ miles W. of Brighton by rail. It is well sheltered on the N. and N.E. by hills, but its chief attractions are its reputed salubrity, its fine and extensive sands, and its long and wide esplanade. W. of the town is the site of Dr. Richardson's proposed 'city of health,' the ground for which has been bought at a cost of £30,000. Pop. (1871) 7413. See G. F. Chambers, *Handbook to the County of Sussex* (Lond. 1877).

Wott'on, Sir Henry, born at Boughton Malherbe, Kent, March 30, 1568, was bred at Winchester, New College, and Queen's, and making the 'grand tour' (1589–97), met at Geneva Beza and Casaubon. Secretary to Essex, he fled, upon Essex's fall, to Tuscany (1600), whose Grand-Duke sent him disguised to Scotland, to warn James VI. of a plot to poison him. James, taking this 'honestest dissembler' into high favour, despatched him on embassies to most of the European courts, and at Venice W. formed a close friendship with Fra Paulo Sarpi, whose *Istoria del Concilio Tridentino* he transmitted to James, sheet by sheet, as it was written. Over-freedom of speech—his saying, namely, that an 'ambassador is a good man and true sent abroad to lie for his country's good'—caused W.'s disgrace, but in 1625 he received the provostship of Eton College, which, with angling and philosophy for recreation, he held till his death in December 1639. Author of poems and sundry treatises, as well as of many sage and quick apothegms, W. chose for his epitaph—'*Hic jacet hujus sententiæ primus auctor: Disputandi Pruritus sit Ecclesiarum Scabies. Nomen alias quære.*' See a Life by Izaak Walton prefixed to his edition of the well-known *Reliquiæ Wottonianæ* (1651).

Woulfe's Bottles, a form of chemical apparatus consisting of bottles of glass or earthenware, fitted with two or three necks, and used in preparing solutions, and in generating gases.

Woulfe's Bottle.

Wounds may be defined as violent solutions of continuity in the soft tissues of the body. Mr. Paget classifies W. as follows:—*Open* and *subcutaneous* W.; the former including those in which the outer part of the wound is almost or quite as extensive as the deeper part; and the latter, all those in which the outer part of the wound is very much smaller than the deeper part. These W. are further divided into (1) *incised* W., such as cuts or incisions, including those which remove a portion of the body; (2) *punctured* W., such as stabs; (3) *contused* W., in which the divided parts are bruised or crushed; (4) *lacerated* W., in which there is tearing of the tissues; (5) *poisoned* W., in which some poison or venom is inserted; and (6) *gunshot* W., which may appear in a great variety of forms.

Simple or *incised* W. are the most common variety. In a clean cut, three phenomena are invariably present, viz., opening or gaping, bleeding, and pain. *Gaping* is caused principally by retraction of the skin; the elastic and cellular or connective tissues; the arteries, muscles, fibrous tissues, nerves, and cartilages. The *bleeding* depends chiefly on the size and number of the vessels divided, and on their connection with the surrounding parts. Regarding *pain*, Mr. Paget says, 'There are differences in both the kind and degree of pain, according to the place and manner of the wound. Thus, in regard to the skin, wounds of the face and of the extremities of the fingers and toes seem to be among the most painful; those of the back amongst the least so; and wounds cut from within are less painful than those from without. The skin appears to be far more sensitive to W. than any of the deeper structures, except the nerves of sensation themselves; but any part (as periosteum or tendons) may become, by disease or distention, highly sensitive.'

When the surfaces of a clean-cut wound are brought into close approximation, and kept so for a sufficient length of time, say from twenty-four to forty-eight hours, there will probably be no appreciable signs of inflammation, and the wound will be so soundly united as to require no further attention, nothing being left except a linear mark, which, in the case of small cuts, may eventually disappear entirely. This method of union is called *primary adhesion* or *immediate union.* In other cases a small quantity of blood is effused from the cut surfaces, which may be either entirely absorbed or a portion of it may become organised; and, in the latter case, the amœboid leucocytes absorb into their tissue material for their nutrition from the neighbouring plasma. Masses of protoplasm are formed, around which a cell-wall is developed; and the nuclei of these cells divide and multiply to form new cells. The rounded cells then elongate into fibre-cells, out of which are formed the fibrous elements of the connective and vascular tissues; the neighbouring vessels shoot out processes into the growing tissue; the unused serum, &c., is reabsorbed, and thus the wound is closed by new material with no formation of pus. This process is called *union by first intention*, or *primary union.* But the inflammatory leucocytes may, instead of developing into fibre-cells and forming tissue, become developed into *pus-globules*, and the exudation break down into a creamy fluid called pus, which consists of these globules floating in serum, the *liquor puris.* The cavity of the wound is closed by the organisation of the processes called 'granulations,' and *union* finally takes place by the *second intention.* In *suppurative union*, or union by the *second intention*, more time is required, there is more destruction of tissue, the bond of union is more lowly organised, and is more prone to degenerations than union by the other modes, and all the symptoms affecting the patient's health are more severe. Some other processes of union are described by Mr. Paget; viz., *union by the third intention*, and *union under a scab.* In the former case perfectly healthy granulating surfaces being brought evenly together throughout, they will adhere without any further suppuration, and thus the wound will be closed perfectly and at once. Union under a scab may take place in fresh W. or in granulating W.

The object to be aimed at in the dressing of W., is to procure, if possible, union by primary adhesion or by the first intention; and, to attain this, various modes of dressing have been proposed. Dr. Humphrey teaches that W. do best when freely exposed to

the air without any dressing; while Professor Lister contends that the air contains all the germs of putrefaction, and that its exclusion is necessary for the rapid and healthy healing of all W. Sir W. Fergusson repudiates all special methods of treating W., and thinks that, as a general rule, they do better with water-dressing than with any other application. Whatever mode of dressing W. is adopted, it is necessary that scrupulous care be taken that all the materials used are clean, and that no impurity can afterwards find access to them. The method proposed by Professor Lister, called the *antiseptic system*, is that which finds most favour with surgeons at the present time. The principles of the method are: (1) to destroy any germs of putrefaction which may have been accidentally implanted in the wound before it is dressed, and to guard against such implantation; (2) never to allow the access of air to the wound except filtered through the antiseptic; and (3) to provide for the drainage of decomposable fluids from the wound without admitting the entrance to it of unfiltered air. For details, see Professor Lister's article in Holme's *System of Surgery*, vol. v. p. 621, 2d ed., and Mr. Paget's article on W. in Holme's *System of Surgery*.

Wou'verman, Philipp, a famous Dutch painter, born at Haarlem in 1620, studied under his father and his countryman Joh. Wynants. He worked hard to support a numerous family, but the traders and not the artist grew rich by his labour. He died at Haarlem, 19th May 1668. He painted landscapes, hunts, horse-fairs, cavalry skirmishes, fishermen and their boats, &c. He was particularly fond of introducing horses, and a white one is a characteristic of his works. All his pictures display a freedom, lightness, and naturalness that can hardly be surpassed. The best collection is in the Royal Gallery of Dresden. There are also fine examples in the Louvre, and in Munich, Vienna, St. Petersburg, Amsterdam, the Hague, Rotterdam, &c. The most complete enumeration of his works is to be found in Smith's *Catalogue Raisonné* (vol. i. Lond. 1829). See Kämmerer, *Ueber die Composition in Philipp W.'s Gemälden* (Lond. 1789).

Wrack, or **Sea-Wrack**, is a general term for the larger kinds of seaweed cast ashore by the waves, but is applied in a special sense to the species of *Fucus*, which form the bulk of the W. collected for manure, and formerly for making kelp. Most of the species are confined to the northern seas, and many grow in situations where they are more or less exposed at low water. The genus is distinguished by having flat or compressed forked fronds; air-vessels when present formed by the occasional swelling of the branches, or in their substance; and receptacles filled with mucus, traversed by a network of jointed filaments (*Berkeley*). *F. serratus* (Black W.), *F. nodosus*, and *F. vesiculosus* (Bladder W.), are as common round the British coasts as grass in the fields. Oxen, sheep, and deer sometimes browse on W. when other food is scarce.

Wrang'el, Friedrich Heinrich Ernst, Graf von, was born at Stettin, April 13, 1784, entered the army in 1796, distinguished himself in the War of Liberation, especially at Hainau and Leipzig, became lieutenant-colonel in 1814 and colonel in the following year. In 1848 he led the Second Corps d'Armée in the Schleswig-Holstein campaign, and in 1849 was appointed to the command of the Third Army Corps. In 1856, on the anniversary of his sixtieth year of military service, he was promoted to the rank of Field-Marshal. In 1864, in the war with Denmark, he held the supreme command of the Austro-Prussian army from January to May, when he resigned it to Prince Friedrich Karl, receiving at the same time the title of 'Graf.' In the war with Austria in 1866 he accompanied the army without holding a command. 'Papa W.,' as the aged veteran was named by the Berlin populace, who loved him for his habitual disregard of grammar, died at Berlin, November 1, 1877.

Wrang'ler. See CAMBRIDGE.

Wrasse, the name applied to a *Teleostean* fish belonging to the family *Labridæ*, in which the mouth is provided with thick fleshy lips. There is one dorsal fin opening in front, and the scales are *cycloid*. The ventral fins are situated beneath the pectorals. The Ballan W. (*Labrus bergylta*) is a familiar species, attaining a length of from 12 to 16 inches. It is red above, and variegated with green on the sides; the fins are green spotted with red, and the abdomen is orange yellow. The Ballan W. is also known by the names 'Ancient W.' and 'Old Wife.' It inhabits the rocky parts of coasts. The *Labrus trimaculatus* or three-spotted W. is another species, of a rich orange hue, and marked with purple and pale rose spots on the back and dorsal fin. The green-streaked W. (*Labrus Donivani*) is a rarer species, named from its peculiar colour.

Wreath (Old Eng. *wrædh*), in heraldry, an addition to the Shield (q. v.), representing two cords of silk, of the two chief cinctures of the arms, twisted together into a roll. The crest is always imposed upon a W., save where it issues from a coronet, or is placed upon a chapeau.

Wreck and Sal'vage. By 17 and 18 Vict. c. 104, when any ship or boat is stranded, or in distress on any shore or tidal water of the United Kingdom, any one assisting to save the lives of those in the endangered vessel, or to save the vessel itself, or its cargo, shall be entitled to receive from the owners a reasonable sum, besides expenses. This payment is called *salvage*. No receiver of wreck is entitled to salvage. Salvage on account of preservation of human life has priority to all other claims for salvage. When a stranded vessel is plundered, the inhabitants of the *hundred*, or district in which the offence is committed, are liable in manner provided by the Act 8 Geo. IV. c. 31.

Wre'de, Karl Philipp Fürst, a Bavarian field-marshal, born at Heidelberg, 29th April 1787. His family was noble, and W. was early employed in state service. In 1793 he was made land commissary in the Palatinate, and in that capacity moved about for five years with the Austrian armies. In 1799 he raised a body of Bavarian volunteers for the Archduke Karl, and took part in the campaigns of 1799 and 1800. He fought at Hohenlinden as a major-general, became lieutenant-general in 1805, and when Bavaria was forced to join France W. fought against his former allies. He commanded a Bavarian division at Wagram, was made a Count of the Empire by Napoleon, and did not abandon the French cause till after the disasters of the Russian campaign. In 1813 he found himself at the head of an Austro-Bavarian army of 70,000 men, and though beaten by the French at Hanau (October 30–31) and at other places, he materially assisted in the advance on Paris, and on the 9th of June 1814 was made field-marshal, and received Ellingen in Nordgau as an hereditary princedom, under Bavarian supremacy. At the Congress of Vienna he worked for the interests of Bavaria, became commander-in-chief of the Bavarian Army in 1822, and died at Ellingen 12th December 1838.

Wren (popularly in parts of Britain 'Kitty W.'), the name given to more than one species of *Insessorial* birds. The typical and common W. is the *Troglodytes vulgaris* of ornithologists, which attains a length of 4 inches. It is of a reddish-brown colour, which becomes pale on the under parts. The eggs are small and number from six to eight, and the entrance to the nest, which is dexterously built, is from the side. The W.'s song is sweet and powerful. Two broods are produced annually. The name W. is applied to other *Insessorial* birds, such as the Emen W. of Australia (*Stipiturus malachurus*), one of the *Malurine* birds, brownish in colour, and remarkable for the development of its tail feathers. The gold-crested W. (*Regulus cristatus*), a common British species, attaining a length of 3 inches, is distinguished by the golden crest of feathers borne on the head, and which it can raise or depress at will. Its upper parts are of a brown colour, tinted with green, the under parts being grey tinted with yellow. The *Regulus ignicapillus* or fire-crested W., allied to the preceding, also occurs in England, but is rarer than the golden-crested W. The Dalmatian Regulus (*R. modestus*) is in turn allied to both. In N. America a species of W. allied to the common European W. occurs. The house W. (*Troglodytes asdon*), and the winter W. (*T. hyemalis*), are also familiar species in the New World. The latter is a bold, pugnacious bird, attacking birds larger than itself, and has even been known to face cats which have approached to its nest. Its average length is 5 inches.

Wren, Sir Christopher, son of a dean of Windsor, was born at East Knoyle, Wiltshire, October 20, 1632, was trained at Westminster school under the famous Dr. Busby, and at the age of fourteen entered as a gentleman-commoner Wadham College, Oxford. Immediately after taking his degree of M.A. he was elected a fellow of All Souls. Already he was giving

proof of his extraordinary universality of talent, as in a long Latin poem, *Zodiacus Reformatus*. His mathematical studies were carried on with men like Dr. Wilkins and Dr. Seth Ward; and the intimacy of the three afterwards gave rise to the Royal Society. In 1657 W. became Gresham professor of astronomy in London, and three years later he obtained the Savilian chair of the same science at Oxford, and soon after the honorary degree of D.C.L. In 1661 he was associated with Sir John Denham, 'clerk of the royal works,' who was a good courtier, a passable poet, but an incompetent architect. W. proved as clever an architect as a mathematician, and in 1663 took a commission for the Oxford Sheldonian Theatre, the roof of which is still a marvel of scientific design. A visit to France at this time brought him into contact with Bernini, Mansard, and other celebrated architects. Having returned to England, he drew plans for the restoration of St. Paul's Cathedral; and these exist in the library of All Souls' College. But the Great Fire made a ruin of St. Paul's, and gave W. the fullest scope for his genius. After spending much time over splendid designs for the wide streets, squares, and quays of a new London, he began to build St. Paul's. He originally planned the edifice as a Greek cross, with a dome as large as that of St. Peter's at Rome. The form of the Latin cross, and other changes, some much for the worse, resulted from the Duke of York's interference. Begun June 21, 1675, St. Paul's took thirty-five years to build; yet its architect lived to see his son put the last stone on the lantern. It ranks next to St. Peter's, and for harmony of exterior effect excels that colossal basilica. W.'s other churches are too numerous to mention; in London alone he erected fifty-three, and of these the best remaining are St. Mary-le-Bow, St. Bride's in Fleet Street, and St. Stephen's, Wallbrook, with its exquisite interior. Of his other buildings may be mentioned Greenwich and Chelsea Hospitals, large portions of the palaces at Hampton Court and St. James's, the west front and towers of Westminster Abbey, the palace at Winchester, and the libraries of Trinity and All Souls. Knighted by Charles II. (1673), he married Faith, daughter of Sir John Coghill (1674), was elected President of the Royal Society (1680), and M.P. for New Windsor (1689). W., however, was not without envious detractors, who brought about his expulsion from all offices at the accession of George I. His latter years were spent at Hampton Court in active study, and he died at table, February 25, 1723, aged 91. 'Si monumentum requiris, circumspice,' are the words over his grave in St. Paul's. W. was the greatest of English architects, and, save Newton, the first mathematician of his time. He possessed a universality of power rare in men of science. He is said to have invented the method of mezzotint engraving, and designed many industrial and scientific instruments which in modern modifications have given fame to others. See *Parentalia*, a volume composed of biographical notes of his son Christopher, edited by his grandson Stephen W. (1750), and Elmes, *Memoirs of the Life and Works of W.* (Lond. 1823).

Wrex'ham, a town of Denbighshire, Wales, on the Gwenfrwry, 12 miles S.S.W. of Chester by rail. The handsome church of St. Giles, in the Perpendicular style (founded 1470), with a tower 135 feet high (finished 1500), and the town-hall, of brick, are the chief buildings. A free library was established in 1878. Collieries, iron mines, lead mines, red sandstone quarries, paper-mills, and breweries abound in the neighbourhood. Large markets are held here, the principal one beginning on March 23. W. unites with Denbigh, Holt, and Ruthin in sending a member to Parliament. Pop. (1871) 8576. W. was long an important town on the Welsh border.

Wright, Thomas, F.S.A., an English author and editor, was born near Ludlow in Shropshire, 21st April 1810, educated at Ludlow Grammar School, and graduated at Trinity College, Cambridge (1834). The year following he settled in London as a man of letters, was one of the founders of the 'Camden Society' (1838), of the 'Percy and Shakespeare Societies' (1840), and of the 'British Archæological Association' (1843), the Journal and publications of which he edited till 1849. W. became a corresponding member of the French Institute (1842), originated the annual archæological congresses in England (1844), and on several occasions successfully conducted local investigations. Napoleon III. chose him to translate his *Histoire de Jules César*. W. died at Chelsea, December 23, 1877. He wrote or edited over 100 volumes, nearly all relating to the history and antiquities of England, and though neither an exact scholar nor a penetrating critic his laborious industry merits praise. Besides editing and annotating many of the best national relics of mediæval literature in English, French, and Latin, he wrote among other original works a *History of Essex* (2 vols. 1831–35), *History of Ludlow and its Neighbourhood* (1841–43; new ed. 1852), *Biographia Literaria* (2 vols. 1842–46), embracing the Old English and Norman periods of our history, *England under the House of Hanover, illustrated from Caricatures, &c.* (2 vols. 1848), *The Celt, the Roman, and the Saxon* (1852; 3d ed. 1875), a *Dictionary of Obsolete and Provincial English* (2 vols. 1857), a *History of Domestic Manners in England during the Middle Ages* (1862), a *History of Caricature and the Grotesque in Literature* (1865), *Homes of Other Days* (1871), *Feudal Manuals of English History* (1872), and *Uriconium, an Historical Account of the Ancient Roman City* (1872).

Wright'ia, a genus of apocynaceous shrubs or climbing aerial-rooting trees, having opposite leaves, flowers in terminal corymbose cymes, and a long cylindrical fruit separating into two folicles, the oblong seeds bearing a tuft of long silky hairs at the base. W. ranges from the Himalaya to W. Australia. *W. tinctoria*, a common Indian species, has a pure white, close, and even-grained wood, much valued for turning and carving, and its leaves yield an indigo. Of *W. tomentosa*, the bark is administered against snake-bites and the stings of scorpions. The root, bark, and seeds of *W. antidysentrica* are astringent, and this tree furnishes a false Conessi Bark (q. v.), the true being the produce of *Holarrhena antidysenterica*.

Writ is a term of English law used to denote a formal document issued either under the private seal of the Courts, and not under the Great Seal of England, and therefore called a '*judicial* W.;' or one issued from Chancery, witnessed in the Queen's name, and known as an '*original* W.' But this distinction almost ceased under the Uniformity of Process Act, 2 W. IV. c. 39.

Wri'ter, in Scotland a term applied generally to legal practitioners in country towns. In Aberdeen these style themselves *Advocates*.

Wri'ters, or Clerks to the Sig'net, an important body of legal practitioners in Edinburgh, are said to have been anciently clerks in the office of the Secretary of State, by whom writs requiring authentication by the king's signet were prepared. When the College of Justice (q. v.) in Scotland was established, the W. to the S. exercised nearly the same functions as at present. Formerly the body possessed important legal privileges; but by the Act 36 and 37 Vict. c. 63 these have become little more than nominal. The Act creates a new body called 'Law Agents,' to which is given the exclusive right of practising before the supreme and inferior law courts of the country. Ordinarily an apprenticeship of five years, with passing of examination, is required for admission to the body; but a term of three years is held sufficient when the candidate is a graduate in law or arts, or when he is an advocate in Scotland, or barrister, or enrolled legal practitioner in England.

Wri'ters' Cramp, or Scriv'eners' Pal'sy, is a condition which occasionally follows the overstraining of groups of muscles, and is met with among those who are engaged in occupations which require the exercise of particular voluntary muscles of the upper and lower extremities to an excessive degree; as clerks, telegraphists, dancers, &c. After fatiguing and long-continued use of the pen, the hand may become at first tired; and afterwards sharp pains may be felt running from the hand up the arm. Dull pains are also felt in the ball of the thumb, the dorsal aspect of the fingers, the wrist, and at the exposed portion of the ulnar nerve at the elbow. There is first impaired writing power, and afterwards, when the individual persists in his attempts, slight convulsive movements. The fingers, forearm, and wrist, more especially the three first fingers of the right hand, may lose power, though sensation is rarely lost or impaired. The same form of cramp affects the thumbs and fingers of telegraphists and the feet of the solo-dancers of the ballet; and a similar affection is met with among violin-players, engravers, stenographers, type-setters, and cigar-makers. W. C. is more rare among those who write and meanwhile compose, than

among clerks and copyists; and the condition is, therefore, the result of an over-developed automatism.

The treatment of W. C. consists in cessation from the occupation which produced the affection, the administration of strychnia and iron, or conium; and excitation by electricity.

Wri'ting. See ALPHABET; CUNEIFORM; HIEROGLYPHICS; PHONETIC WRITING.

Wrong'ous Impris'onment, in Scotch law, is the illegal detention of the person either through violent seizure or through a breach of the rules that regulate legal procedure. The individual thus wrongously imprisoned has redress both at common law and by special statute. See FALSE IMPRISONMENT.

Wry'neck (*Yunx torquilla*), a species of *Scansorial* bird belonging to the family *Picidæ* or woodpeckers. It is a summer visitant in Britain, appearing about the same time as the cuckoo, and hence called 'cuckoo's mate.' It is about seven inches long, of a brown colour above, mixed with grey tints, and a dull brownish-white below. The eggs are laid usually in the hollow of a tree. The W. subsists chiefly on insects, for the capture of which its tongue is specially adapted.

Wry'neck is a common deformity in children from spastic contraction of the sternomastoid muscle by which the head is drawn towards the shoulder, and the chin turned to the opposite side. The contracted muscle stands out strongly under the skin, and sometimes the size of the features on the affected side is strikingly less than on the opposite. If the deformity be neglected, the clavicle itself may yield and be curved upwards. The trapezius, scalene, and other muscles are involved, but to a less extent. W. is usually due to congenital causes, though it may not be noticed till some years after birth. The only effective treatment consists in the division of the sternomastoid muscle by two punctures. The head should be put well on the stretch, and the knife should be entered behind the clavicular fibres, about half an inch above the clavicle, and passed beneath the muscle. Then its edge is turned towards the fibres, and they are divided completely. The same operation is performed with the sternal tendon. The head is afterwards kept in position by a suitable apparatus.

Instances of W. sometimes occur among children, depending either on irritation from worms, or on some cerebral cause difficult to detect, but somewhat analogous to hysteria. If the child be put under chloroform the deformity will disappear, showing that there is no shortening of the muscle. Adults sometimes suffer from spasmodic W., and the disease may be due to irritation propagated from the medulla along the spinal accessory nerve. W. is often also purely hysterical, and such cases are most difficult to treat.

Wupp'erthal, the busiest and most densely-populated valley of the German Empire, receives its name from the winding Wupper or Wipper, which, after a course of 64 miles, enters the Rhine between Koln and Düsseldorf. By W. is sometimes understood only the district between and embracing Barmen (q. v.) and Elberfeld (q. v.), which, since the intervening 4 miles of road are lined continuously by houses and factories, have come to be regarded as a single town, with a pop. (1875) of 167,071. Oftener, however, it is extended to the entire basin of the Wupper and its tributaries, and so comprises Remscheid (q. v.), Lüttringshausen (q. v.), Solingen (q. v.), Höhscheid (q. v.), Merscheid (pop. 10,017), Lennep (pop. 7753), &c., the pop. of the W. thus understood exceeding 324,000 persons, occupied chiefly in spinning, weaving, bleaching, dyeing, and iron-founding. The W. has not escaped the widespread manufacturing depression of recent years, the Barmen district exporting to the United States goods to the value of only £1,175,000 in 1876, against £1,275,000 in 1875.

Wurd'ha (*Wardha*), the chief town of the district of the same name, Central Provinces, British India, on the left bank of the W. river, 40 miles S.W. of Nagpur and 471 E. of Bombay. It was only founded in 1866; but as a station on the railway it has already become a centre of the cotton trade. The *district*, which was formed out of Nagpur in 1862, has an area of 2401 sq. miles; pop. (1872) 354,720. The staple crops are millet, cotton, wheat, and rice. Here is produced the well-known Hingunghat cotton, which is exported to the amount of 25,000 bales (of 400 lbs. each) a year. In 1875-76 the trade in cotton was valued at £41,000, and in country cloth at £19,000. The breed of cattle is good, especially the trotting bullocks. The railway now crosses the centre of the district.—The **W.** *river* rises in the Satpura hills, and flows S.E. for 254 miles to join the Weingunga; the united stream, under the name of the Pranhita, ultimately falls into the Godavery at Sironcha.

Wur'no, a town of the Central African state of Sókoto (q. v.), on the river Sókoto, 18 miles N.E. of the town of that name. It has a considerable trade in cotton, corn, and kola nuts. Pop. estimated at 12,000.

Wuro'ra (*Warora*), a town in the district of Chanda, Central Provinces, British India, on the left bank of the Wurdha river, 28 miles S.E. of Wurdhatown. Here is one of the largest coalfields in the peninsula. A shaft has been sunk, which passes through a coal-seam 15½ feet thick at a depth of 176 feet, and a little lower through another seam 11 feet thick. It is estimated that the field may afford an output of 100,000 tons per annum for 100 years. A narrow-gauge line (46 miles long) has been laid down to W. from Wurdha station on the Great Indian Peninsula Railway; capital expenditure up to 1877, £455,000; net earnings, £1989.

Würt'emberg (officially *Württemberg*, formerly *Wirtemberg*), a kingdom of S. Germany, bounded N. by Bavaria and Baden, W. and S. by the same countries, the Bodensee and Hohenzollern, and E. by Bavaria. Area, 7675 sq. miles; pop. (December 1, 1875) 1,881,505 (1,296,750 Protestants, 567,578 Catholics, and 12,881 Jews). The emigration to America, which in 1872-74 drew off 5000 a year, declined in 1875, and nearly ceased in 1876. The chief mountain-districts of W. are the Schwarzwald (q. v.), which occupies the W. part of the country, rising in the Hornisgrinde (locally called the Katzenkopf) to 3775 feet; the Alp (q. v.) or Swabian Jura, a wooded range of limestone mountains, which stretches in a N.E. direction towards Bavaria between the Danube and the Neckar, and whose highest points are in the S.W., the Oberhohenberg (3313 feet), the Lemberg (3326 feet), and the Plettenberg (3293 feet). To the N. of the Alp, and on both sides of the Neckar, extends a mountainous tract formed of numerous small groups under different local names, and nowhere rising above 1800 feet; to the S. of the Danube is a plateau averaging 1500-1900 feet high, with here and there heights, of which some rise to 2400 feet; and in the S.E. of the Donaukreis the Adelegg, culminating in the Schwarzegrat or Schwarzkopf (3644 feet). W. belongs partly to the basin of the Danube (q. v.), of whose course 90 miles are in W., but chiefly to that of the Rhine, which receives the Neckar (q. v.), the Murg, Kinzig, and Tauber. The Wilhelmskanal makes the Neckar navigable from Kronstadt to Heilbronn. Geologically, the Alp is Trias topped by the Jura formation, the 'Swabian and Franconian terrace-land' is Muschelkalk and Upper New Red Sandstone, and between Stuttgart and Reutlingen is Upper New Red topped by black Jura or Lias. The sole mineral products of W., exclusive of some alum and iron-vitriol, are salt and iron. The eighteen iron mines worked in 1876 produced 28,284 tons of ore, yielding 10,816 tons of pig-iron, valued at £186,104; while the salt prepared in the same year was 72,158 tons, worth £65,872. The climate of W. is temperate, averaging 45·6° F. In 1876 there were in W. 3410 sq. miles under tillage, employing about one-half of the population. The chief cereal crops were spelt (263,424 tons), oats (156,476 tons), barley (136,074 tons), rye (36,963 tons), and wheat (21,988 tons). In the same year were produced 717,593 tons of potatoes, and 519,072 tons of various kinds of beetroot, while the hay crop amounted to 1,024,400 tons. W. also produces rape-seed, hops, flax, and hemp. The vine is extensively cultivated. In the fifty years 1827-76 the average yield of wine was 9,645,196 gallons, valued at £411,858. Fruits are abundant, chiefly apples, pears, plums, cherries, quinces, peaches, apricots, nuts, and chestnuts. Forests (52 per cent. of coniferous trees) cover 2273 sq. miles. There were in W., in 1873, 96,970 horses, 946,228 head of cattle, 577,290 sheep, 267,350 swine, and 38,305 goats. The industries of W., which in 1875 employed 200,000 persons, consist of the manufacture of cottons (£2,000,000 worth a year), woollens and half-woollens, linens (£825,000 a year), hardware, gold, silver, copper, and brass wares, paper (7759 tons annually, worth £300,000), steam-

engines and other machinery, philosophical instruments, organs, pianos (27,000 a year), and harmoniums (the last two to the value of £150,000 annually), silks, lace, embroidery, corsets, leather and leather gloves, straw-plait, toys, chemicals, colours, gunpowder, beet-sugar, confectionery, chicory, and 'Schaumwein.' The chief imports are colonial products, southern fruits, oil, tobacco, hemp, hardware, hides, soap, cotton, coal, glass, and fancy goods. The railways of W.—all, except 11 miles, belonging to the state—covered (1877) 815 miles; telegraphs in 1874, 509 miles. The 'Evangelical Protestant Church' of W. was formed in 1823 by a union of the Lutherans and Calvinists ('Reformed'), and its direction is in the hands of six general superintendents, under the King. The Catholics are under the Bishop of Rottenburg, who acts in conjunction with a 'Kirchenrath' appointed by the Government. Education is in a very forward state. No one above the age of ten is unable to read or write. Children between the ages of seven and fourteen are obliged to attend the 'Volkschulen,' which in 1876 numbered 2500, having 3910 teachers and 350,000 scholars. For secondary education there are 70 'Latin schools,' 7 lyceums, and 9 gymnasiums, together attended (1876) by 7700 pupils; and 79 'Realschulen,' with (1876) 7607 pupils. W. is well supplied with technical and art schools, and has over 1000 industrial schools. For theological students there are 4 Protestant seminaries, and the famous 'stift' at Tübingen (q. v.), the seat of the university. There are also 3 Catholic 'Konvicte,' and a seminary at Rottenburg. W. is a constitutional and a hereditary monarchy. The legislative power is vested in the 'Landtag' of two houses —the 'Standesherren' (45 members), and the 'Abgeordneten' (93), and the executive in a privy council of six ministerial departments. The army of W. forms the 13th corps of the Imperial army (in 1878, 17,745 men). The total revenue and expenditure in 1877-78 each amounted to £2,416,939, and the public debt (1st July 1878) was £16,660,738 (£14,386,743 on railways). See *Württembergische Jahrbücher für Statistik und Landeskunde* (Stuttg. 1818 *et seq.*); Pleibel, *Handbuch der Vaterlandskunde* (2d ed. Stuttg. 1877); *Die Gemeinschaften und Sekten W.'s* (Tüb. 1877).

History.—The earliest known inhabitants of W. were the *Suevi*, among whom the Romans, after the conquest of their country about 84 A.D., founded several settlements. The Alemanni having thence expelled the Romans about the middle of the 3d c., were conquered by Hlodwig at Zülpich in 496 Under the Frankish rule the country was divided between Rheinfranken and the duchy of Schwaben, which existed till the fall of the House of Hohenstaufen in 1286. With the Graf Ulrich in 1241 begins the historic series of the grafs of *W.* Eberhard VII. was made Duke of W. in 1495. In 1520 W. came under the Hapsburg dominion, but recovered its independence in 1534 under Duke Ulrich, in whose time the Reformation began to be introduced. W. having in 1633 leagued with Sweden against the Emperor, was devastated by the imperial troops. It suffered a like treatment from the French under Melac (1688–92). Under Eberhard Ludwig (1693–1733) W. was governed by the court mistresses, and under Karl Alexander (1733–37) by the Jew Süss-Oppenheimer, but Karl Eugen's (1744–93) struggle for absolute power was wisely checked by the 'Erbvergleich' of 1770. Involved in war with France in 1796, W. was forced to yield Mömpelgard, in compensation for which Friedrich II. Wilhelm Karl received in 1803 the title of Elector, with extensive additions to his territory, called *Neu-W.* By an alliance with Napoleon on the 5th October 1805 and the 1st January 1806, the Elector became King of W., which received much further extension, and became a member of the Confederation of the Rhine. In May 1809, Ulm and Mergentheim were also added. After the battle of Leipzig W. broke with Napoleon in the Treaty of Fulda (November 1813), and joined the other German princes. King Wilhelm (1816–64), though he granted a liberal constitution (September 25, 1819), pursued in the main a policy in sympathy with Austria. Karl I., his successor, siding with Austria in 1866, was defeated at Tauberbischofsheim (24th July), and on the 13th August concluded peace with Prussia, paying eight million florins of war indemnity, and entering into an offensive and defensive alliance with Prussia. See the histories of W. by Pfister (5 vols. 1803–27), Pfaff (new ed. 3 vols. 1835–39), and Stälin (4 vols. 1841–73), the last being the most important. There is a short abstract of the history of W. by Staiger (Tüb. 1875).

Würz'burg, a town of Lower Franconia, Bavaria, Germany on the Main, 22 miles S. of Schweinfurth by rail. It is pleasantly situated chiefly on the right side of the river, which is crossed by a fine bridge 500 feet long. The chief buildings are the Royal Palace, a very splendid structure erected in 1722-44, with a large square in front of it, and extensive gardens behind. The cathedral, a Romanesque basilica, in the middle of the town, was founded in 742, rebuilt in 1042, and restored in 1852–53. The Marienkapelle (1377–1479), St. Burkhardt (1033–42), on the left bank, the Neümünster-kirche (1000), whose crypt contains the relics of St. Kilian, where Walther von der Vogelweide (q. v.) was buried, and the Renaissance Hauger-Stiftskirche (1670–91), are the finest of 32 churches. W. has a university founded by Bishop Julius in 1582, with (1878) 69 instructors and 941 students, over one-third medical, there being here an excellent hospital, the Julius Hospital, with 500 patients. The university has a library of over 100,000 volumes, and the hospital has a very extensive museum. W. was till lately fortified, but its ramparts have been converted into boulevards. The fortress of Marienberg (1650) on the hill outside the town was till 1720 the episcopal palace. It is a place of no strength, but contains a large garrison. Wines, woollens, and scientific implements are manufactured, and there is trade in corn, wine, beer, timber, &c. Pop. (1875) 44,975, of whom 7666 were Protestants and 1879 Jews. W. is historically interesting as the capital of the sovereign bishopric of W., founded in 741 when the town was already existing; Burkhardt was the first bishop; the Irish St. Kilian was the patron saint. It was besieged and destroyed in 1080 by Prince Hermann, but soon revived, and ducal rights were conferred on the bishops in 1120. Again on 7th May 1525 the Bavarians took the town, and the citadel surrendered in a month. Gustaf Adolf besieged it 18th October 1631. Secularised (1801) by the peace of Luneville, it was given to Bavaria in 1803. The last engagement of the Prussian army of the Main during the six weeks' war was the bombardment of the fortress, 27th July 1866. The see, long vacant owing to the *Cultur Kampf*, was at last filled up in May 1879. See *W. und seine Umgebungen*, by Heffner (2d ed. Würzb. 1871); *Die Herzogliche Gewalt der Bischöfe in W.* by Henner (Würzb. 1874); and *Baugeschichte Würzburgs* by Urlichs (Würzb. 1878).

Würz'zen, a town of the kingdom of Saxony, on the Mulde, 16 miles E. of Leipzig by rail. It has a cathedral, founded at the beginning of the 12th c., and two other churches, a schloss of the 15th c., flour, oil, and paper mills, and manufactures of carpets, felt, cigars, chemicals, and pottery. Pop. (1875) 8165 (almost all Protestants). W. was a city as early as 961. It was sacked and partly burnt by the Swedes in 1637.

Wy'andots, the 'Hurons' of French writers, a tribe of N. American Indians of the Iroquois stock. They originally dwelt in Canada, W. of Montreal, but were nearly exterminated in 1636. A few settled at *Ancien Lorette*, in Lower Canada, where they still remain and are called Hurons. The rest wandered about in the United States near Lake Superior, furnished 300 fighting men to England in 1812, and now occupy a reservation in Indian territory. Part of the tribe has accepted United States' citizenship, and are prospering greatly; the remainder (220 strong in 1870) are less flourishing.

Wy'andotte, a town of Kansas, U.S., at the confluence of the Missouri and Kansas rivers, opposite Kansas city, has 8 churches, a State blind asylum, 2 weekly newspapers, &c. W. is an important railway junction, and the seat of great machine-shops, stock-yards, rolling-mills, and pork and beef packing-houses. The neighbourhood is rich in coal, and the town has been lighted since 1867 by gas from a natural gas-well. Pop. (1870) 4791.

Wy'att, Richard John, an English sculptor, born in London, 3d May 1795, became a pupil of Charles Rossi, R.A., and afterwards a student of the Royal Academy, whose medal he twice carried off. W. settled at Rome in 1821, and died there 28th May 1850. He was an artist of high and refined talent, and worked with extraordinary industry. Among his best-known works are his 'Flora,' 'Nymphs,' 'Penelope,' 'Ino and the Infant Bacchus,' 'Musidora,' and 'A Shepherd Boy protecting his Sister from the Storm.' His female figures in particular are singularly happy in their combination of emotional expression and physical beauty.

Wy'att, Wyat, or **Wiat, Sir Thomas,** an English poet, born in 1503 at Allington Castle, in Kent, was the son of Sir Henry W., who about ten years later distinguished himself at the Battle of the Spurs. Having entered St. John's College, Cambridge, in 1515, he took his B.A. degree in 1518, and became M.A. in 1520. After his marriage, which also belongs to 1520, we have little trace of him till he appears as ewerer at the coronation of Anne Boleyn, who, according to a vague conjecture, had been the object of his passion. By this time he was in favour at court as a gentleman of rare endowments and attainments, well suited 'to serve his prince at all assays.' In 1537 he was knighted, and though he was imprisoned for a short time in the Tower on account of a quarrel with the Duke of Suffolk, he was soon after assured of the royal confidence by being not only made Sheriff of Kent, but commissioned as ambassador to the Emperor Karl V. in Spain. In 1539 he was employed to frustrate the coalition of France and Spain, then earnestly laboured after by Cardinal Pole. Soon after his return to England Cromwell fell, and as one of Cromwell's friends he was accused by Bonner of treasonable dealings. So conclusive, however, was his defence, that he was not only set at liberty, but the king, in token of his satisfaction, crowned him with favours and rewards. Retiring to Allington 'to walk at liberty in lusty leas, and in foul weather at his books to sit,' he doubtless looked forward to many pleasant years; but in 1542 he was called to meet an imperial embassy at Falmouth, and being exposed to bad weather on the way, fell sick at Shelbourne, where he died on the 10th or 11th of October. W.'s importance as a writer is due mainly to the fact that along with Surrey (q. v.), his younger compeer, he marks the Renaissance of English poetry. The effects of foreign culture are evident in his workmanship, and indeed a number of his pieces are free translations from the Italian; but, except in a few cases, when he is carried away by a free lyrical impulse, he has failed to catch the melody of his masters. Yet the poems are not destitute of beauty and force both of emotion and phrase. They are mainly of the amatory type, and many were certainly written before 1536. The three satires after the manner of Horace, and the version of the penitential psalms, belong to the last years of his life. His defence against Bonner is impassioned and able. W.'s works are usually associated with Surrey's. Nott's (1815–16) is probably the best edition; Gilfillan's, Bell's, and Hannah's (in *Courtly Poets*, 1870) are among the more recent. See Nott's *Life of W.*; Edward A. Bond's paper on a Wyatt MS. in *Athenæum* (1871); and Minto's *Characteristics of English Poets* (Lond. 1874).—**Sir Thomas W.**, surnamed 'the Younger,' son of the preceding, was born about 1520, served with distinction on the Continent (1544–50), but has acquired a place in history as the leader of the passionate revolt of the Kentish men (1554), when the news reached them that Queen Mary was bent on marrying Philip of Spain. W. forced his way victoriously to Southwark, but finding the bridge over the river secured, crossed at Kingston. Cut off from his followers, though he pushed on with desperate courage as far as Temple Bar, he sank exhausted at the gate, was taken prisoner, and sent to the block 11th April 1554.

Wych'erley, William, born at Clive, near Shrewsbury, about 1640, was sent to France by his father, a country gentleman, when fifteen years of age. Madame Rambouillet, among others, patronised the handsome young fellow, and her influence made him a Romanist. About the period of the Restoration W. returned to England, and while living at Oxford as a private student he became Protestant again for convenience's sake, although he died a Papist, according to Pope. He next went to London as a law-student, but, like so many clever young fellows of the period, found play-writing the occupation most productive of public encouragement. He told Pope that his *Love in a Wood* was written when he was nineteen, but it appeared only in 1672. The Duchess of Cleveland went two successive nights to see it performed, accepted its dedication, and introduced the author to court favour. Scandal says he rose to the highest point in her own. The only good action that was ever attributed to this dramatist was an endeavour to secure for the author of *Hudibras* the patronage he himself enjoyed, but he failed. Meantime the king gave him smiles and sometimes money, while Buckingham commissioned him in his own regiment. W.'s life about town was so successful that he only required to write three other plays,—*The Gentleman Dancing-Master* (1673), *The Country Wife* (1675), and *The Plain Dealer* (1677). This last is much the best of his smart, vigorous, indecent comedies. While the dramatist was in a book-shop at Tunbridge Wells the Countess of Drogheda came to ask for *The Plain Dealer*. 'There he is,' said the bookseller, pushing forward W., who eventually married the lady. While she lived he was plagued with her jealousy, and when she died, her disputed fortune only led him into law expenses, by which he was reduced to seven years of the Fleet prison. After the accession of James II. a royal pension of £200 was granted him, and the inheritance of the paternal estate restored him to the bosom of vicious London society. In 1704 he furbished up a volume of wretched *Miscellany Poems*. To spite his heir-at-law the old debauchee married a young girl eleven days before his death, 1st January 1715. His *Posthumous Works* were published in 1728. The first complete edition of W.'s works appeared at London in 1712; later editions are those of 1720, 1731, 1735, and 1768, and Leigh Hunt's (Lond. 1840; new ed. 1865). The best thing that can be said of W. is that he served as a model for Congreve and Farquhar. See Macaulay's *Essay on the Comic Dramatists of the Restoration*.

Wy'combe, High, or **Chipping,** a town of Buckinghamshire, England, on the Wye, 15 miles N. of Windsor by rail. It consists mainly of a long street; its parish church of All-Saints was built in 1273, in the Norman style, has undergone frequent alterations, and was restored in 1875. The making of chairs, lace, and strawplait are the leading industries. There are several paper-mills on the Wye. Pop. (1871) 4811. The village of West W., 2½ miles N.W., carries on the same industries, and like High W. has numerous traces of Roman occupation. The two towns form the major portion of the parliamentary borough of W., which has had one member since 1867.

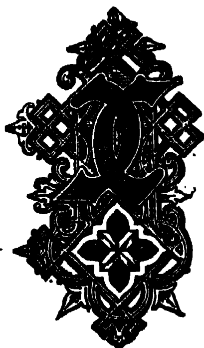
Wye (Cymr. *gwy*, 'water'), a river of S. Wales, which, rising in Montgomeryshire, amid the swamps of Plinlimmon, not 2 miles from the Severn's source, and flowing generally S.E. between Radnor and Brecon, through Hereford, and between Gloucester and Monmouth, enters the Severn at Chepstow, 123 miles below its head. Rapid and rockbound as far as Hay, the W. grows gentler as it gathers volume, but throughout is singularly beautiful, making innumerable horse-shoe curves between wooded banks, and passing by Maeslough, Clifford, Goodrich, and Chepstow Castles, Hereford Cathedral, and Tintern Abbey. A pair-oar can descend from Hay, and barges ascend as high as Hereford, but a tidal-bore, whose height on 8th April 1879 was 44 feet, makes navigation dangerous at the mouth, where netting has greatly spoilt the upper salmon-fisheries. See Ritchie's *Upper W.* (Lond. 1839), illustrated by Creswick, and Howitt's *Ruined Abbeys and Castles of the W.* (Lond. 1863).

Wyke'ham, William of, was born at Wykeham, Hampshire, in the summer of 1324; his patronymic, if such indeed he had, being Longe. Of humble birth, he owed a training at Winchester high school to the liberality of Nicholas Uvedale, lord of the manor of Wykeham and constable of Winchester Castle; and having served as secretary first to that nobleman and next to Bishop Edynton of Winchester, he gained through their patronage a place about court (1348). Appointed by Edward III. clerk of the royal works (1356), he built Queenborough Castle in the Isle of Sheppy; a nobler proof of his grand powers as architect was the rebuilding of Windsor Castle, where, however, the presumptuous legend, 'Thys made Wykeham,' set up in a conspicuous place, had brought him into trouble with the king, but for the explanation that Windsor Castle was the making of *him*. Meanwhile from deacon's (1352) he rose to priest's orders in the next ten years, and received (1357) the Norfolk rectory of Pulham, first in a long series of church preferments, including a deanery, archdeaconry, and seventeen canonries. In 1359 he became chief warden and surveyor of sundry royal castles and manors, in 1363 warden of the king's forests on this side Trent, in 1364 keeper of the privy seal and secretary to Edward III. Charged with three others to negotiate the ransom of the captive David II. (1365), he was raised to the see of Winchester (1366), and within a twelvemonth created Lord High Chancellor. 'In those days,' says Froissart, 'there reigned in England a priest called W. of W., who was so much in favour with the king that everything was done by him, and nothing was done without him.' But his 'reign' was soon

clouded by the political troubles of Edward's closing years, and having in 1371 resigned both the great and the privy seals to creatures of the baronage, he was accused in 1376 of embezzlement, oppression, and other acts of misgovernment. The accusation fell through after costing him 10,000 marks; and from the restoration of his episcopal castles and reformation of the religious houses throughout his diocese, including the ancient hospital of St. Cross, W. could turn to the great object of his life—the founding of the two great colleges of New College (q. v.) and Winchester (q. v.). 'Wherein I am wanting myself,' ran his speech in 1366, 'that will I supply by a brood of more scholars than all the prelates of England ever showed;' and W. College was first of its kind, a pattern to Eton and all succeeding public schools. To study the scriptures and grammar, 'the foundation-stone, gateway, and source of all other arts and sciences,' is the main precept of W.'s wise and liberal statutes, where Wykehamists are led to esteem no man's person, but themselves to observe that courtly bearing set forth in the founder's motto, 'Manners makyth man.' New College was opened in 1386, Winchester in 1393; and W., having again been chancellor (1389-91), died at South Waltham, 27th September 1404, and was buried in his cathedral, the nave of which he was then re-building. See his Life by Bishop Lowth (new ed. Oxf. 1777), and Walcott's *W. of W. and his Colleges* (Lond. 1852).

Wynaud' (*Wainád*), a mountainous tract in the interior of the district of Malabar, Madras, British India, on the inner side of the W. Ghauts, sloping E. towards the States of Coorg and Mysore. Area, about 1190 sq. miles. For long this tract was only known as covered with primeval jungle, but in 1840 a coffee plantation was experimentally commenced. In 1862 there were nearly 10,000 acres under this crop. By 1873 the cultivation had increased to 29,595 acres, in 6913 holdings, of which 195 belong to Europeans; the total produce is estimated at 83,500 cwts. The industry is of a speculative nature; virgin land is sometimes bought at from £4 to £6 per acre, cleared at great cost, and then again suffered to go to waste, owing to a fall in prices. Labour is attracted by the high rate of wages from the neighbouring tracts, and the planters themselves only live on their estates during certain seasons. During the last few years a new form of speculation has sprung up. Gold had long been obtained from alluvial deposits, but it has now been ascertained that there are auriferous quartz reefs yielding an average proportion of 7 dwts. of gold to each ton of quartz.

Wyn'toun, Androw of, a Scottish chronicler, was born about the middle of the 14th c. He was a canon regular of the priory of St. Andrews, and in or before 1395 was elected prior of the monastery of St. Serf's Insh in Lochleven, one of the earliest religious establishments in the E. of Scotland. The date of his death is unknown. His *Orygynale Cronykil*, undertaken at the request of his friend Schyr Jhone of the Wemyss, ancestor of the Earls of Wemyss, appears from internal evidence to have been finished about 1426, and therefore belongs to the reign of James I. It is a metrical history in nine books. 'W., like most other historians of his own and the preceding ages, begins his work at the creation; and he gives a general history of the world in the first five books, with very little of Scottish or British history till the commencement of the sixth; after which he gradually drops foreign affairs, and comes home to the proper business of his undertaking.' The work is in many respects an invaluable record. It contains what must be regarded as the original account of many historical transactions, and there is evidence of an unprejudiced, impartial, and modest spirit in the author himself; but there is hardly any poetry in W.'s octosyllabics. The diction, however, has a philological if not an artistic value, and merits the careful attention of all students of the English tongue. The best MS. of the *Orygynale Cronykil* is the 'Royal' in the British Museum. In modern times the work was first brought before the notice of the public by Dr. William Nicolson, Bishop of Carlisle, in his *Scottish Historical Library* (1702). It was also described by Dr. George Mackenzie in his *Lives and Characters* (1708), but was first printed in 1795 by Mr. David Macpherson. This editor was thoroughly qualified for the task, but he chose to omit the books which did not bear on Scottish history. However valueless these might be, their suppression was a mistake, and they have been restored in Mr. Laing's version of Macpherson's edition, forming 3 vols. (Paterson, Edinb. 1872-79) of the 'Historians of Scotland.'



Wyo'ming, a territory of the United States N. of Utah and Colorado, and W. of Nebraska and Dakota. It is rectangular, measures 355 miles by 276, and has an area of 97,883 sq. miles. Pop. (1870) 9118 (estimated, December 1874, at 25,000). The Rocky Mountains cross the territory in a south-westerly direction, and its surface is generally mountainous. The Big Horn River flowing N. but afterwards E. to the Missouri, and the N. fork of the Plate running E. to the Mississippi, are the two largest streams, but the whole country is well supplied with water. Gold and silver are found in various places, chiefly W. of Fort Cheyenne. Iron and coal are already worked in large quantity. Copper, lead, and gypsum are known to abound. The annual rainfall is small, averaging only 11 inches. With a mean annual temperature, 44° F., the climate of W. is healthy—genial and temperate in summer, though in winter stormy and severe. The Union Pacific Railway traverses the S. part of W. for 470 miles, passing Cheyenne, the capital. Pines clothe the hills, while the elm, ash, walnut, &c., are also plentiful. Part of the territory belongs to the great American Desert and is covered with buffalo grass, but it is estimated that 5,000,000 acres are readily available for arable land and 35,000,000 for pasture. The grizzly bear, wolf, badger, elk, buffalo, antelope, mountain-sheep, and various deer, are the chief wild animals. Horses and cattle are rapidly multiplying on the farms. Grouse and other game abound, while the rivers are well stocked with trout and salmon. An immense area in the N.W. upwards of 50 miles square is reserved as the Yellowstone National Park (see UNITED STATES). In regard to a district changing so rapidly as W., statistics have little value. In 1874 it was estimated that upwards of $500,000 worth of cattle were sent from W. to Chicago. In that year the territory contained 14 schools. In 1875 there were 17 churches and 10 newspapers—3 were published daily. The first settlement was made in 1836, and W. was organised as a territory in 1868. Cheyenne, the capital, had an estimated pop. of 2500 in 1874, but is rapidly growing. See *North-Western W., including Yellowstone National Bank*, by W. A. Jones, Captain U.S.A. (Wash. 1873; Lond. Trübner).

Wyo'ming (Ind. 'great plain'), the name of a valley on the W. branch of the Susquehanna, Pennsylvania, U.S., 21 miles long by 3 broad, and closed in by lofty cliffs. It was always noted for fertility, and latterly rich coal-seams have been found in it. On 30th June 1778, 400 British troops, 700 Seneca Indians, and a few 'Tories,' *i.e.*, American royalists, under Colonel John Butler, invaded the valley, and only 300—mostly lads and old men—could be mustered by Colonel Zabulon Butler to defend the place. The battle of W.—fought on July 3d—ended in the defeat of the latter, and was followed by great cruelties. Campbell's *Gertrude of Wyoming* is in many respects grossly inaccurate, his knowledge having been derived chiefly from vague rumours. A monument at Kingston commemorates those who fell in the battle of W. See C. Miness, *History of W.* (1845), and George Peck's *W., its History and Incidents, &c.* (New York 1858).

Wyr'cestre, William, son of a Bristol burgess of the same name, was born in that city in 1415, entered Hart Hall (now Balliol College), Oxford, in 1432, where he remained four years, and afterwards became secretary and pursuivant to Sir John Fastolf, in commemoration of whose exploits he wrote the *Acta Domini Johannis Fastolf*, which Bale had seen and quotes, but which is now lost. He was one of Fastolf's executors, and the administration of the will brought him into controversy with Sir John Paston and others. The dispute was not settled till 1472. In 1473 he presented his friend, Bishop Waynflete, with a copy of an English version which he had made of Cicero's *De Senectute*, and which was published anonymously by Caxton. He died in Bristol about 1479. The twin passions of his life were literature and architecture. His chief works are the *Itineraria* (edited by Nasmith, 1778), and the *Annales Rerum Anglicarum, 1324-1468* (edited by Hearne, 1771). The *Saturday Review* (January 18, 1879), in an interesting notice of W., says that if Leland is the father, W. is the forefather of English antiquaries. 'The numerous waifs and strays of hagiology, biography, and folk-lore, as well as of topography and contemporary history, that are to be found only in W., commend his unpretending books to more attention from the student of mediæval history than they have received.'

Wytt'enbach, Daniel Albert, born 7th August 1746 at Bern, studied at Marburg, Göttingen, and Leyden, and was successively professor of Greek at the Remonstrants' College at Amsterdam (1771), of philosophy at the Athenæum there (1779), and of eloquence at the University of Leyden (1799). Retiring in 1816, he resided first at Heidelberg, then at Leyden, and died at Œsgeest, 17th January 1820. W.'s writings are full of sound classical learning and criticism, expressed in pure and clear Latin. The chief are *Epistola Critica ad D. Ruhnkenium* (Gött. 1769); *Præcepta Philosophiæ Logicæ* (Amst. 1782; new ed. by Maas, Halle 1821); *Vita Ruhnkenii* (Leid. 1800; last ed. by Frotscher, Freiburg 1846); the *Bibliotheca Critica* (3 vols. Amst. 1777-1808); the *Philomathia seu Miscellanea Doctrina* (3 vols. Amst. 1809-17); his editions of Plato's *Phædo* (Leid. 1810, Leip. 1825) and Plutarch's *Moralia* (5 vols. Oxf. 1795-1800), and the *Animadversiones* (3 vols. Oxf. 1810-21). A collection of his *Opuscula Varii Argumenti* appeared after his death (2 vols. Leid. 1821); selections by Friedemann (Brunsw. 1825), as also of his *Index Græcitatis* (2 vols. Oxf. 1830), and his letters, *Epistolarum Selectarum Fasciculi Tres* (edited by Mahne, Ghent 1830). See Mahne, *Vita D. Wyttenbachii* (Ghent 1823).—**Johanna W.** (*née* **Gallien**), married to the above in his seventy-second year, lived after her husband's death chiefly in Paris, obtained the degree of doctor of philosophy from Marburg University in 1827, and died at Leiden in 1830. Of her writings the chief are *Théagène* (Par. 1815); *Das Gastmahl des Leontis* (Ulm 1821), and the novel *Alexis* (Par. 1823).

X.

The twenty-fourth letter of the English alphabet. It is a double consonant, compounded with *s* and one of the gutturals. It first appears in the Greek alphabet at a comparatively late period, and thence it came into Latin. When used as an initial it generally betrays a Greek origin. It almost universally represents a guttural, but sometimes another letter compounded with *s*, as Lat. *nix* 'snow' from root *niv*; *proximus* 'nearest,' from root *prop*. Sometimes again it stands for simple *s*, as Gr. *sun* and *xun*; Lat. *Ajax*, Gr. *Aias*. In Spanish it is pronounced as a guttural aspirate; *cf. xeres* 'sherry.' As a numeral X stands for ten, perhaps as representing a V standing upon a second V inverted. In Latin it was a common symbol for *denarius*. As an algebraic symbol it is used to represent the unknown quantity to be determined.

Xan'thein, a name given by Fremy and Cloez to one of the three colouring principles discovered by them in flowers, the other two being called *Xanthin* and *Cyanin*. X. and xanthin are yellow, soluble and insoluble in water respectively, and cyanin is blue in colour.

Xan'thine ($C_5H_4N_4O_2$), a natural base present in nearly every part of the animal organism, and in minute quantities in urine. It was first described under the name of xanthic oxide by Marcet, who discovered it in urinary calculi. It may be prepared with great facility from Guanine (q. v.) by treating that substance with nitric acid. This action gives rise to X. and another substance, nitroxanthine, which by the action of reducing agents is reduced to X. also. X. is a white, amorphous powder, hardly soluble in water, but forming with acids crystalline compounds. It dissolves in nitric acid without evolution of gases, and also dissolves readily in ammonia and potash. When evaporated from solution in nitric acid there is left behind a deep yellow characteristic precipitate.

Xanthox'ylon, or Zanthox'ylum, a large genus of *Rutaceæ* representative of the tribe *Xanthoxyleæ*. The species have a wide geographical range, and they differ much in habit, some being trees, while others are erect or climbing shrubs. The fruits of most have an aromatic pungent taste like pepper. In the United States the bark of *X. fraxineum* (toothache shrub or prickly ash) is used as a permanent arterial stimulant, and as an alterative in syphilis and rheumatism; and in the W. Indies that of *X. clava-Herculis* is used for malignant ulcers, and is employed both externally and internally as an alterative in syphilis. Its stem is valued for walking-sticks, and the beautiful close-grained wood serves for inlaid work, &c. The fruit of *X. alatum* of India is used as a remedy for toothache, and as a condiment, and when bruised is put into foul water to purify it; the bark has the power of intoxicating fish.

Xan'thus, the ancient capital of Lycia (q. v.), was situated in the fertile plain of the river X., on its left bank, and 6 miles above its mouth. Twice destroyed, by the Persians under Harpagus in 546, and by the Romans under Brutus in 43 B.C., it never recovered from the latter blow; but its ruins, near the village of Kounik, remain to attest its former grandeur. Cyclopean in their character, these comprise a theatre, temples, and rock-cut tombs, and were first explored by Sir Charles Fellows (q. v.) in 1838-42. The Zendic inscriptions of the monuments, first deciphered by Grotefend, have most recently been discussed in Schmidt's *Lykische Inschriften* (Jena 1868).

Xantipp'e, wife of Socrates, is the typical female termagant or scold. Most of the stories about her are probably false; for in ancient Athens gossip was cultivated to the perfection of a fine art, and the *point* and not the *truth* of the story was the chief consideration. X. had probably some little acerbities of temper, and these must have been heightened by the peculiarities of her spouse, especially his indifference to the commonplace duty laid upon the head of the house to make both ends meet. Socrates received her reproaches with such good-humoured indifference that we cannot wonder she sometimes resorted to other weapons beside her tongue; as on the occasion when she is said to have finished up a tirade by sousing the philosopher, though his remark, as he moved dripping from the scene, that when X. thundered she watered, must have convinced her that here too she was powerless. Some authors have given Socrates a second wife, entitled Myrto, but the story is undoubtedly false. In our own day, Zeller has given X. an elaborate whitewashing (*Vorträge und Abhandlungen*, 2d ed. Leip. 1875); but the opinion of mankind will, we are afraid, still be that of the Old English writer who calls her 'a passing shrewde, curste, and wayward woman, wife to the pacient and wise philosopher Socrates.'

Xavier, Francisco (the modern Spanish spelling of the name is Javier, and the pronunciation Havier), a missionary and saint of the Roman Catholic Church, usually styled the Apostle of the Indies. He was a native of Northern Spain, being the son of a nobleman whose family seat of Xavier lay to the N.W. of Pampeluna. The date of his birth is probably 1497, and not as it is frequently given, 1506. At the College of Sainte Barbe, in Paris, he attained while still young some importance as a lecturer on philosophy; but a friendship which he formed with his fellow-countryman Loyola turned his attention in a new direction, and he became one of the first members of the Society of Jesus. In the early part of 1540, before the society had received papal approbation, he was chosen for the mission to India, and received the title of apostolic nuncio from Paul III. The rest of his life was consecrated with high-souled devotion to the work of an evangelist. From Goa, his headquarters, where he arrived in May 1542, he extended his labours southwards to Ceylon, Malacca, and Celebes. The last two years of his life were spent in Japan, where he met with remarkable success, and he was on his way to China when he fell ill with fever, and was abandoned to his fate on the island of Sancian by the shipmen with whom he sailed. He expired on the 2d December 1552. His body was conveyed to Goa, where it still remains without corruption in the church of the Bom Jesus. Once in a century it is shown to the people on the saint's day, the 3d of December. The last occasion was in 1878. X. was canonised in 1619, and in 1747 Benedict XIV. declared him the Protector of India. His letters are printed in Bartolus, *Historia gestorum per Jesuitas in Asia* (Rome 1665). See besides the works of Tursellinus (Antw. 1598), and Bouhours (Par. 1621); Verne, *Life of Francis X.* (Lond. 1863); Coleridge, *Life and Letters of X.* (2 vols. Lond. 1872-73); De Vos, *Leben und Briefe des heiligen F. X.* (2 vols. Regenb. 1877); J. M. Macanaz in *Revista de la Universidad de Madrid* (1874); Isabella Burton, *A. E. I., Arabia, Egypt, India* (Lond. 1879); and *The Graphic* (March 22, 1879).

Xe'bec (Fr. *chebec*, Port. *xabeco*, from Turk. *sumbeki*), a small three-masted vessel used in the Mediterranean Sea. It is rigged either with square or lateen sails. Xebecs carrying from sixteen to twenty-four guns were formerly used by Algerian pirates.

Xe'nia, a town of Ohio, U.S., 65 miles N.E. of Cincinnati, is an important railway junction, and has 13 churches, a fine court-house and city building, 3 newspapers, and numerous edu-

cational institutions, including a Methodist Episcopal College (1850), with 230 students (1876). In its neighbourhood are the Ohio Soldiers' and Sailors' Orphanage (1870), a county infirmary, and the Wilberforce University (1863). X. has large manufacturing establishments. Pop. (1870) 6377.

Xenoc'rates, a Grecian philosopher, born at Chalcedon, B.C. 395, was one of the followers of Plato, and *Scholarch* or chief director of the Old Academy (339-314), as the first development of Plato's school was called. 'The one' and the 'Indefinite Duad' he affirmed to be the basis of existence. The soul was 'self-moving number,' and happiness resulted 'from the possession of the virtue proper to use and of power devoted to its service.' These definitions and principles show that X. built up his philosophy by piecing together fragments from the systems of his predecessors. See Wynpersse, *Diatrebe de Xenocrate Chalcedonis* (Leyden, 1822), and Ueberweg, *Geschichte der Philosophie* (Eng. trans. by Morris, 1874).

Xenoph'anes, the founder of the Eleatic School of Philosophy, was born at Colophon about 569 B.C., and wandered as a Rhapsodist through Greece. He lived to a great age, though the exact period of his death is uncertain. In direct contrast to his philosophical predecessors on the one hand, and to the popular beliefs on the other, he held the doctrine of the Unity of Being. The 'One' alone exists, and this one he called God. He did not attempt to explain the contradictions to which the theory of Unity gave rise, and for the complete development of his philosophy we must look to his successor Parmenides (q. v.). See the Histories of Philosophy by Schwegler, Ueberweg, and Lewes.

Xen'ophon, one of the best known of the Greek class of authors, was born at Athens about 444 B.C. His father, Gryllus, was a man of position, and consequently X. received a good education. He was one of the pupils of Socrates, and this was of itself the highest sort of training a man could have. When about forty he joined the expedition of Cyrus against Artaxerxes. On his return he settled at a charming retreat at Scillus in Eleia, and gave himself up to literature and the sports peculiar to a country life. These sports he seems to have followed and described with equal relish. He died either at Scillus or at Corinth about 357. X. wrote a considerable number of works, and all of these, it would seem, have come down to us. The chief are— the *Anabasis*, in 7 books, which relates the expedition of Cyrus already referred to. It falls conveniently into three parts. The first relates how Cyrus invaded the Persian dominions of his brother Artaxerxes, and how he lost his life at the battle of Cunaxa (401); the second is an account of the retreat of the Greek contingent, 10,000 strong, through an hostile and unknown country, and in the presence of difficulties of all sorts, to the Euxine. X. was chosen one of the leaders to conduct the retreat, and this he managed, according to his own account, with a happy combination of prudence, courage, and skill; the third part tells the subsequent adventures of the contingent. The *Memorabilia* is a record, in 4 books, of the life and teaching of Socrates. This is for us by far the most important work of X. In it he defends his master from the charges brought against him by showing in a plain matter-of-fact way that he did *not* corrupt the youth, and that he *did* sacrifice to the state divinities. A great number of conversations and incidents in the life of Socrates are described with considerable minuteness; but we miss in the account some of the most remarkable characteristics of the great philosopher. The delicate irony, the rich humour, the subtle play of thought, are absent, or shine with but feeble lustre, in X.'s narrative. Still the work is very valuable, for (1) any scrap of information about Socrates is valuable, (2) and this account seems quite accurate, as far as it goes, (3) it enables us to 'check' the Platonic picture which otherwise would have seemed like so many other Platonic ideals, a dream never to be realised in this life. Along with the *Memorabilia*, the *Apology* and *Symposium* must be taken. The one is the speech of Socrates before his judges, the other is a picture of a classic feast, at which Socrates is one of the chief characters. They are among the most pleasing of the works of X., but unfortunately Plato has two dialogues of the same name, which are so far beyond them as works of art that they have quite eclipsed them. The other works of X. need not detain us long. The *Hellenica* in 7 books gives us a somewhat dull and dry account of forty-eight years of Grecian history. It is a continuation of Thucydides (q. v.), and terminates B.C. 362. The *Cyropædia* in 8 books is a fictitious biography of Cyrus of Persia (not the Cyrus mentioned in the *Anabasis*). It is merely a political romance in which historical propriety is not observed, for the whole surroundings are thoroughly non-Persian. It has been well said of its purpose that 'a combination of the teachings of Socrates with the institutions of Sparta is what X. wishes to recommend under the shallow disguise of Persian names and the picture of a foreign court.' The *Agesilaus* is a somewhat exaggerated panegyric on the Spartan tyrant of that name. The *Revenues of Athens*, the treatises on the *Spartan and Athenian States* are works on economy and politics based on perfectly outrageous principles which we can only pardon when we remember that Aristotle had not yet written. The *Hiero* is a dialogue on the advantages and disadvantages of a kingly station. In the *Hipparcus*, a treatise on the duties of a commander of cavalry, in the *Horse*, a dissertation on ancient jockeyship, and in the *Cynegeticus*, a discourse on hunting, as well as in the *Œconomics* on household management, the practical X. is quite at home; nowhere is he more entertaining or more sensible, and nowhere does he appear to better advantage. Of X. generally it may be said, that of all the classic writers he is the most commonplace. He had considerable experience, and his remarks on men and manners are no doubt true, but they are only skin deep. He was a plain blunt soldier with a very 'flat' turn of mind. A great hero-worshipper, too, though not a very discriminating one, since characters so different as Socrates, the younger Cyrus, and Agesilaus were alike the objects of his laudation. Quite a man of the world, he is yet not at all of a sceptical disposition. He carefully consulted the oracles on doubtful occasions, though he generally took very material means to make the response 'square' with his preconceived intentions. Why after all this does he occupy the place he does in the literature of the world? Many reasons might be given, and these would naturally be the record of his merits. He was a man of strong, though not of great, mind. He is sensible, lively, and natural; moreover, he is one of our best sources of information regarding some of the most important events that have ever happened and the greatest people the world has ever seen. His style is a model of the purest Attic Greek. The first collected edition of X.'s works with a preface by Ph. Melanchthon was published in 1540. Of later editions the best are by Schneider (6 vols. Leip. 1825-49), Bornemann, Kühner, and Breitenbach (4 vols. Gotha and Erfurt, 1828-54), and Dindorf (Par. 1839). Of the translation of separate works that of the *Memorabilia* by Levien in the 'Bayard Series,' and that of the *Economics*, with introduction by Ruskin, forming the first volume of the *Bibliotheca Pastorum*, merit special mention. For notices of the Life of X. see Krüger, *De Xenophontis Vita Quæstiones Criticæ* (Halle 1822). In the study of X., Sturz's *Lexicon Xenophonteum* (4 vols. Leip. 1801-4) and Dodwell's *Chronologia Xenophontea* will be found useful. A popular account is given by Sir Alexander Grant in his *X.* (Edin. 1871) in Blackwood's 'Ancient Classics for English Readers.'

Xeres de la Frontera, a town in the province of Cadiz, Spain, on the Guadalete, 27 miles N.N.E. of Cadiz by rail. It is a well-built, active, and growing town, with good churches and schools, a theatre, and a great arena for bull-fights. Cloth and leather are manufactured; corn, wool, and wine are exported. Wine is the staple. The hills around are clothed with vines. Of the 4,541,076 imperial gallons of sherry (named from this town) which X. exported in 1877, 3,968,028 went to British ports and colonies. Pop. (*Almanach de Gotha* 1879) 52,158. The *Asta Regia* of the Romans, X. was the scene of a great battle, 19th July 711, between the Gothic King Roderick and Tarik the Saracen.

Xeres de los Caballeros, a town of Spain, province of Badajos, on the Ardila, 40 miles S. of Badajos. It is picturesquely situated at the foot of the Sierra Morena, well built, and partially surrounded by old Moorish walls. X. has numerous churches and convents, woollen manufactures, and trade in agricultural produce. Pop. 8000.

Xeroder'ma. See FISH-SKIN DISEASE.

Xerx'es, a celebrated Persian king, who ruled from B.C. 485 to 465, was the son of Darius, and immediately on his accession prepared to carry out the invasion of Greece, the preparations for which had been begun by his father. These preparations were on the most enormous scale. Provisions were stored up

on the intended route for three years previously, an enormous transport fleet was collected, the engineering skill of the day was exerted to remove land obstacles, and the resources of the vast Persian empire were taxed to the utmost to produce an armament sufficient (it was thought) utterly to crush Greece. According to the computation of Herodotus, the invading army consisted of over two and a half million combatants and at least as many non-combatants; and although this, of course, is a huge exaggeration, we must hold it to have been the (numerically) greatest army on record. At the head of his enormous host X. advanced unopposed till he came to Thermopylæ; but here his fleet was seriously damaged by a storm, while the passage of the narrow pass was effectually prevented by Leonidas, at the head of a determined though small band of Spartans. At last the passage was effected through treachery, and X. marched on through Phocis and Bœotia to Athens, which he entered without opposition. In the meantime the Persian fleet had met with several mishaps. In two engagements with the Greek ships at Artemisium it had suffered considerable damage, and a storm which happened between the two conflicts was the cause of still greater loss. Finally, at Salamis (480 B.C.) was fought a naval battle, one of the most decisive in the history of the world. The Persians were defeated with terrible loss, and X., who from a lofty eminence had watched the destruction of his fleet, gave up the command of the invading army to Mardonius, and fled panic-stricken to Sardis. He spent the rest of his life in inglorious obscurity, and was finally murdered by Artabanus, the commander of his body-guard, who was plotting to make himself king of Persia.

Xim'enes, Gonsa'lez, afterwards **Francis'cus de Cisneros,** Spanish cardinal and statesman, was born of a noble though poor family, at the little town of Tordelaguna in 1436. He studied at the University of Salamanca, where he took the degree of bachelor both of civil and canon law. In 1455 he went to Rome, where he pled the cause of his countrymen in the consistorial courts with such success that he attracted the attention of the then pontiff. He returned in 1461 with an *expective*, which gave him a right to the first ecclesiastical preferment in a certain see that should fall vacant. A suitable office did fall vacant in 1473, but Carillo, Archbishop of Toledo, wished to fill it with a creature of his own. X. refused to surrender his rights, whereupon the enraged prelate shut him up in prison for six years. X. refused to yield, and at last attained his rights. Preferments of one kind and another followed; but X. finally determined to leave the ranks of the secular for those of the regular clergy. He became a Franciscan, one of the straitest of sects. But in vain he attempted to escape from the world. He was appointed guardian of the convent of Salzeda, in 1492 chaplain to Queen Isabella, and in 1495 Archbishop of Toledo. He was now an old man of sixty, but more than a lifetime's work lay before him. He engaged in important civil and clerical reforms, and these his determined energy enabled him to carry through in the face of much opposition. He founded the University of Alcala (1500), endowed it magnificently, and made provision therein for the encouragement of every liberal art. He collected a body of learned men and a vast number of important manuscripts, and with such aid he compiled the famous polyglot Bible known as the *Complutensian Polyglot*, a work which took fifteen years, and cost a vast sum of money. He projected also an edition of Aristotle, but this his manifold labours did not allow him to complete. He violently converted a large number of the 'infidels' of Grenada to the 'true faith,' and he carried on a victorious campaign against the Moors of N. Africa. On 17th May 1507 he was appointed cardinal, and when Ferdinand died in 1516 he ruled as regent for the young Carlos (afterwards known as Karl V.) the whole of Spain. Here his prudent care disarmed the hostility of Ferdinand, the younger brother of Carlos (a youth whose pretensions to the crown were favoured by many of the people), reconciled a discontented nobility, filled the royal treasury, and maintained the army and navy in a high state of efficiency. His regency lasted about two years. Then Carlos left the Netherlands for Spain. Almost his first act of sovereignty was the dismissal of the faithful regent. X. was already on his deathbed, and it is doubtful if he ever knew of the act of the king. He died at Toledo, 8th November 1517. X. lived not for himself but for his country, and still more for his Church. Without selfish motives or loose passions, he was worthy to be a prelate of imperial Rome and a statesman of imperial Spain. Whilst clad in the almost royal purple of a cardinal, he still wore, beneath, the coarse mean robe of his order; and this was a fit type of his life, for whilst the one prefigured his vast power, the other still more aptly signified the life-long martyrdom of a soul that longed to be free; a martyrdom, historians tell us, that showed itself in the lines of a noble face furrowed with care and sorrow. See Prescott's *Ferdinand and Isabella*; *De Rebus Gestis a X. libri octo, auctore Alvaro Gomecio*; Robles' *Vida y Hazañas del Card. X.* (Toledo 1604); and Fléchier, *Hist. du Card. X.* (Paris 1631). There is an English life by Barret (London 1813).

Xin'gu, a large river of Brazil, rises in the eastern spurs of the Serra Diamantina, near the heart of the country, and after flowing N. and N.E. for fully 1300 miles through a fertile but undeveloped region, joins the Amazon 210 miles W. of Para (q. v.).

Xiphosu'ra, an order of *Crustacea* (q. v.) represented solely by the king crabs or *Limuli*, found in the West Indian seas, and also in the East Archipelago. The front segments of the body are united to form a broad shield-like plate or *carapace* of convex shape, whilst the posterior portion is elongated to form a terminal, sword-like, spinous tail (*telson*), from the presence of which the name X., or 'sword-tailed,' has been given. On the upper and convex surface of the 'carapace' are placed the eyes, whilst the concave or under surface bears the locomotive and other appendages. In the Limulus there are thirteen pairs of appendages, and of these, six pairs, in the form of legs, are attached round the margin of the oral aperture, the spines with which the basal or proximal joints of the legs are furnished subserving the function of a masticatory apparatus. Anteriorly, and in front of the mouth, a pair of chelate antennæ are also situated. The remaining feet are placed posteriorly on the abdominal surface in the form of broad plate-like structures, to which the respiratory organs are attached. The extinct group of the *Eurypterida* were closely related to the X. The two genera, *Pterygotus* and *Eurypterus*, are included in this group, the most familiar form being that of the *Pterygotus Anglicus*. Like the *Trilobites*, the *Eurypterida* are solely characteristic of the Palæozoic life-period.

Xylene', or **Xylol'** (C_8H_{10}), one of the aromatic hydrocarbons, being a homologue of benzene (C_6H_6), and sometimes known as dimethyl-benzene from the supposition that it is formed from benzene by the substitution of two molecules of methyl (CH_3) for two hydrogen atoms. It is a colourless liquid, boiling at 140° C. When passed through a red-hot tube, X. is resolved into a mixture of several homologous hydrocarbons, the composition of which is of the type C_nH_{2n-6}.

Xylo'bius (Gr. *xylon*, 'wood,' and *bios*, 'life'), a fossil genus of *Myriapoda* (q. v.) occurring in rocks of Carboniferous age, within the hollowed trunks of *Sigillaria*, one of the most characteristic trees of the Coal Epoch. X. had the power of rolling itself up for protection into a ball-shaped form.

Xyloï'din ($C_6H_9(NO_2)O_5$), a dry white tasteless substance, into which starch is changed when treated with nitric acid. Chemically considered, it is a substitution product in which one hydrogen atom is replaced by the radical nitryle (NO_2). It is insoluble in water, but dissolves freely in dilute nitric acid. In composition and method of formation it resembles Pyroxiline (q. v.), the active constituent of gun-cotton.

Xyloph'aga (Gr. 'wood-eaters'), the name applied (1) to a group of beetles resembling the weevils, but destitute of a beak, and noted for their habit of excavating wood; (2) to a family of Diptera or flies, of which the chief genus is *Xylophagus*. In this group the antennæ are ten-jointed, and there is a long ovipositor. The larva is cylindrical, and has a scaly plate on the tail, the head ending in an acute point.

Y.

The twenty-fifth letter of the English alphabet, and like W. both a consonant and a vowel. Its form is derived from the Greek Υ, and it is first found at a late date in the Latin alphabet to transliterate the sound of U, which vowel had come to be pronounced almost the same as I. *Cf.* Odusseus = Ulysses. Its vowel use in English is merely a superfluous substitute for I, especially at the end of a word, as 'glory' from Lat. *gloria.* Its consonantal sound is properly a softened form of J, which letter in German is pronounced like our Y: *Cf.* Lat. *jugum* = Ger. *joch*, 'yoke;' hyacinth = *jacinth.* In Middle and Modern English it often represents an Old English G; *e.g.*, 'young' = Old Eng. 'geong;' 'year' = Old Eng. 'gear.' The participial prefix 'ge,' common to German and Old English, passed in Middle English into Y.—*e.g.*, 'For he was late *ycome* (Old Eng. *gecumen*) from his viage' (Chaucer, Prol. to *Canterbury Tales*). This transition shows the close connection between the vowel and consonantal sounds of the letter.

Yablonoi' Mountains. See SIBERIA.

Yacht (Dutch *jagt*, 'a light chasing ship,' from *jagten*, 'to chase') **and Yacht'ing.** A yacht is a light swift-sailing vessel, elegantly fitted up for pleasure-trips or racing. State pleasure-boats of the 17th c. were called 'yachts.' In 1720, 'The Water Club,' the parent of British yachting clubs, was founded at Cork, and it still exists as the 'Royal Cork Yachting Club.' Yachting made little progress for a century. In 1801 there were probably not more than 20 yachts owned by private individuals in Great Britain. Now (1879) the British yacht navy comprehends upwards of 2000 vessels from 3 to 600 tons or thereby. 1400 yachts exceed 10 tons, the average tonnage being 45 tons. They are classed according to their rig as schooners, cutters, and yawls, the first being the largest. Sailing efficiency is sometimes supplemented by steam-power, and the tonnage of these steam-yachts often exceeds that of the largest sailing-yachts. Next in point of age to the 'Royal Cork Club' ranks the renowned 'Royal Yacht Squadron,' which was founded (as 'The Yacht Club') at Cowes in 1815 by fifty yachtsmen. The 'Royal Thames Yacht Club' dates from 1823, and the 'London Yacht Club' (originally the 'Arundel Yacht Club') from 1838. There are now upwards of 50 clubs, more than one-half bearing the title 'Royal,' established around the British coasts, and every season they hold regattas, which are made the occasion of local fêting. These clubs form a splendid nursery for daring seamen, and they accordingly receive encouragement from the Admiralty. Among other privileges, they are allowed to refit and revictual in royal dockyards, and to use the ensign of the royal navy in addition to a distinctive club flag. Yachting is likewise cultivated in many foreign countries, especially in the United States, where racing-yachts have been brought to a high pitch of perfection. Early British yachts were constructed on the plan of the revenue cutters of the period, but gradually the heavy build was abandoned and lighter scantlings used. In 1851 the celebrated schooner-yacht *America* (210 tons), constructed by Steers of New York, appeared in British waters, and carried off the best prizes of the season, including 'The Queen's Cup' at Cowes Regatta. Her success was correctly attributed to her peculiar build and the splendid cut of her sails, which were made of cotton instead of flax. Racing-yachts then became the rage, and English yacht-builders constructed them after the general plan of the *America*, adopting her shallow keel, fine lines fore and aft, and light frame. Through fastenings were also dispensed with at the risk of weakness; the flooring was altered to give increased space for carrying a large quantity of ballast on any given displacement, and the increased stability arising from this change enabled a larger area of canvas to be carried. Strength and durability have been in a great measure sacrificed to the exigencies of yacht-racing, and the need for supervising the construction of yachts has of late years become pressing. Accordingly in 1878, Lloyd's society formed a 'Yacht Register,' and issued a set of rules for the construction, equipment, and classing of wood, composite, and iron yachts, on the plan of supervision organised for the merchant navy. Since 1851 there have been several interesting Anglo-American yachting matches, in most of which the American yachts maintained their superiority. In May 1870 the famous American schooner-yacht *Sappho*, 394 tons, defeated the splendid English schooner yacht *Cambria*, 188 tons, in three matches in the English Channel—two to windward and one over a triangular course. In the following July (4th to 27th) victory attended the *Cambria* in an ocean race from Daunts' Rock, S. of Ireland, to New York, which destination she reached 1½ hours in advance of her larger opponent, the American schooner yacht *Dauntless.* While in America, the *Cambria* endeavoured at the regatta of the New York Yachting Club to wrest the 'Queen's Cup' won at Cowes in 1851, but failed. An important trans-Atlantic race took place in December 1866 between three American schooner yachts, the *Henrietta*, 201 tons, *Fleetwing*, 205 tons, and the *Vesta*, 212 tons, and was won by the first-named vessel by a few hours. The voyage occupied only fourteen days. The love of adventure leads British yachtsmen to undertake voyages of no ordinary character, as circumnavigating the world (recently performed by Mr. Brassey in the *Sunbeam*), or penetrating the Arctic regions.

Yak (*Bos* or *Poephagus grunniens*), a species of Bovidæ or Oxen, inhabiting Tibet and the higher plateaus of the Himalayas. There are several varieties, which have been produced through the domestication of the animal. The appearance of the Y. is highly characteristic. Its shoulders are markedly humped, the rump is low, and the legs short. The shoulders are provided with a massive 'mane,' and the tail is extremely bushy. The breast is also provided with a large hairy tuft. The colour is usually black, and the animal attains the size of an ordinary ox. The specific name *grunniens* was given from the low grunting sound which the animal emits. The milk of the Y. is rich and plentiful, the flesh is highly valued, and from the hair several kinds of cloths and fabrics are made. The tail, mounted in silver, is used as a *chowrie* or fly-flapper in India. Of the varieties the noble Y. is the largest breed, the plough Y. being smaller and more docile. The animal may be crossed with domestic cattle. The Y. is employed as a beast of burden, and traverses mountainous districts with great ease. The horns are curved somewhat sharply upwards, and when irritated, the animal uses them as a means of offence. The calves do not develop the characteristic hairy covering until they are three months old or more, and their flesh is especially tender and palatable. The Y. has been domesticated for centuries in Central Asia, and the khans and lamas of Tibet measure their wealth by the number of their Y. flocks.

Yakutsk'. See JAKUTSK.

Yak'ub Beg, surnamed *Khushbegi* ('lord of the family'), and *Atalik Ghazi* ('victorious guardian'), was born near Samarcand early in the present century. His lineage and race are doubtful, but he originally appears as chamberlain to Khudayar Khan, the Mohammedan conqueror of Khokand, then a Chinese possession.

He became successively a commander of five hundred soldiers, governor of the Ak Musjid ('White Mosque'), on the Jaxartes, where in 1853 he stubbornly resisted the advance of the Russian general Perovsky, and governor of Kurama. At this time Y. B. had the reputation of being a brave soldier, an orthodox Mohammedan, and a stern disciplinarian. But he first rose to great eminence after the recovery of Kashgar from the Chinese in 1864. In the course of three years he had firmly established his power. For twelve years this remarkable man conferred on a large part of Central Asia the benefits of a settled though rigorous government. He 'drilled and disciplined a large civil staff. He presented to his subjects the spectacle about which Indian administrators now and then dream, of a monarch who held a public durbar to which the meanest had access, who received all kinds of petitions, who passed orders by a sort of instinct on piles of reports, who punished delinquent officials for malpractices, who whipped vagrants and beggars, drove idlers to say their prayers at mosques, checked sedition, and forced women to go about in modest veils' (*Saturday Review*, January 11, 1879). In his foreign policy he was strongly anti-Russian, and ultimately friendly to Britain. In 1874 a commercial treaty was concluded between Y. B. and Sir Douglas Forsyth to develop intercourse between India and Kashgar, which has already (see YARKAND) produced considerable results. But in the spring of 1877 he was assassinated, though another account attributes his death to fever, and the fabric he had so laboriously raised fell to pieces almost immediately. The Chinese armies overran the country (1878), and Kashgar has again come under Chinese rule. See Demetrius Charles Boulger's *Life of Yacoob Beg, Ameer of Kashgar* (Lond. 1878).

Yak'ub Khan, Mahomed, Ameer of Afghanistan, is the eldest surviving son of Shere Ali (q. v.) by the daughter of a Momund chief, and was born about 1848. He was nominated heir to the throne of Cabul in 1864. Appointed governor of Herat, he became extremely popular, and succeeded in maintaining his father's authority in that province when the rest of Afghanistan passed under the rule of the rival Ameers, Afzul and Azim. It was owing to his admirable generalship that Shere Ali regained his throne in 1868, and when the latter visited India in the following year Y. K. was appointed governor of the capital. In 1870 he was made governor of Candahar, and afterwards was sent a second time to Herat, where, however, his great influence excited the fears and suspicions of Shere Ali, who now declared his youngest son, Abdullah Jan, to be his heir, and sought to prejudice the British Government against Y. K., by falsely representing him as hostile to British interests. Captain Marsh, who visited him at Herat in 1872, found him exactly the reverse. In 1873 Shere Ali recalled him from Herat, Y. K. declined to return, and for a year was practically in revolt. At length, under the most sacred pledges of safety, he proceeded to Cabul, but was treacherously imprisoned, and was only released when the flight of his father before the victorious advance of the British arms in the War of 1878 made his presence indispensable to prevent anarchy in the capital and the State. On the death of Shere Ali he succeeded to the throne, and on the 30th May 1879 concluded a Treaty of Peace with the British. Shortly after the murder of Cavagnari in the following September, he fled to the army that General Roberts hurried forward to punish the Cabul assassins, and is detained a prisoner by the Indian Government.

Yale College, at New Haven, Connecticut, U.S., was chartered by the General Assembly of Connecticut in 1701, and next year a commencement was made at Saybrook. It was removed to New Haven in 1716, and two years after, in recognition of the benefactions of Elihu Yale, a Londoner, took its present name of Yale College. A new charter was granted in 1745, and further alterations were made in 1871. The college is governed by trustees, who include the president, the governor and lieutenant-governor of Connecticut, six elected graduates, and ten Congregational clergymen elected by the Fellows. The president was for 100 years the chief teacher. A professor of divinity was appointed in 1755, and a professor of mathematics in 1770. The present buildings occupy a square in the centre of the city (850 feet by 400). The endowment amounts to $700,000. There are four faculties or 'departments of instruction'—(1) of theology, organised 1822; (2) of law, 1824; (3) of medicine, 1812; and (4) of philosophy and the arts, which last includes (*a*) the academical department—the original school; (*b*) the Sheffield Scientific School, 1847; (*c*) the school of the fine arts, 1864; and (*d*) the school of graduate, non-professional instruction, a system of extra-mural teaching. 1. The Theological Faculty, in connection with the Congregational Church, was organised in 1822; the course extends over three years, and the education is gratuitous. 2. The Faculty of Law, begun privately in 1800, was organised in 1824; the course for the degree of LL.B. extends over three years (annual tuition fee $90): another year's study qualifies for Master of Laws, and a fifth for Doctor of Civil Law. 3. The Medical Faculty, organised in 1813, gives the degree of M.D. after a two years' course (annual tuition fee $105). 4. Faculty of Philosophy and the Arts (*a*) academical department; the course extends over four years (annual tuition fee $140); the degrees are B.A., Ph.B., M.A., Ph.D.; (*b*) Sheffield Scientific School; course three years for degree of Ph.B. in agriculture or mechanics. Bachelors of Arts may get Ph.D. after two years' study, and M.A. after one. In session 1876-77 Y. C. had 87 instructors; 95 theological, 60 law, 36 medical, 569 academic department, 206 scientific school, 16 fine arts, and 67 graduate students. Nearly 11,000 alumni have left its halls. There is a college library of 80,000 vols., a Linnæan Society library of 20,000 vols., and special libraries of 17,000 vols. The Peabody Museum was founded in 1866 (endowment $150,000). The President (1879) is Noah Porter (q. v.).

Yam, the name given to the fleshy tubers of several species of *Dioscorea* extensively used for food in many tropical and subtropical countries, where they are also largely cultivated. The genus consists of upwards of 150 species of herbaceous perennials or undershrubs with twining stems, leaves mostly entire with strongly-marked veins, flowers inconspicuous, arranged in spikes, fruit with membranous wings. There is much resemblance both in chemical composition and in the taste between the Y. and the potato. The following are some of the best-known species; the two first being grown to the greatest extent. (1) The Uvi-Y. of India and South Sea Islands (*D. alata*), also successfully cultivated in New Zealand and in the southern United States. The tubers, of which there are many varieties, will under favourable circumstances attain a length of 8 feet and a weight of 100 lbs.; they may be eaten baked or boiled. (2) *D. aculeata*, in which the stem is prickly, and unlike the above, does not require artificial support; it also ripens later than *D. alata*, has a sweet taste, and is spoken of as one of the finest esculent roots of the globe. It is found in India, Cochin-China, and South Sea Islands. (3) *D. hastifolia*, of W. Australia, found as far S. as 32°. The tubers are largely consumed by the aborigines for food, indeed it is the only plant on which they bestow any cultivation. (4) The hardy Chinese or Japan Y. (*D. Japonica* or *D. batatas*), which has been introduced into Algeria, S. France, and Australia, where it is reported to be of easy cultivation and to yield a prolific crop. (5) The Tivoli Y. (*D. nummularia*), a high-climbing prickly species; the roots are cylindrical, and their taste is 'exceedingly good.' (6) *D. pentaphylla*, a good Y.; the flowers of which are used as greens. (7) *D. purpurea*, Pondicherry potato, considered in Bengal the next best Y. to *D. alata*. (8) The root of it yields *D. sativa* of S. Asia, &c., which requires soaking before boiling; about 24 per cent. of starch. (9) *D. trifida*, cultivated in Central America. (10) *D. villosa*, called wild Y. or colic root, said to be a specific for bilious colic, and also used as an anti-spasmodic.

Ya'ma, the Hindu god of departed spirits, and the appointed judge and punisher of the dead. He thus exercised larger functions than the corresponding personage in Greek mythology, Pluto. His name occurs in the Vedas, and his image is still a common object of worship, represented with a grim countenance, riding on a buffalo.

Yambô', or **Yanbo'** (from its situation on the Red Sea coast also called *Y.-el-Bahr*), a town of the province of Hedjas, Arabia, and the harbour of Medina, which lies 131 miles to the E. It consists of a long row of white houses built of limestone and coralline, standing on the edge of an arid plain. It has considerable imports and transit trade between Suez, Jidda, and Medina. Marking the end of the third quarter of the caravan journey from Cairo to Mecca, Y. bears the title 'Gate of the Holy City.'

Yan'aon, or **Yan'am**, a French settlement in India, on the Telinga coast of the Bay of Bengal. It lies at the head of the

delta of the Godavery river, 9 miles above the sea, and is entirely surrounded by the British district of Godavery, in the Madras Presidency. The maritime trade is insignificant. The settlement is known to have been founded before 1750, and has more than once been occupied by the British. In 1839 it was devastated by a cyclone and storm-wave which destroyed all the official records. Area 2258 acres; pop. 5460; revenue £4550.

Yang-tsi-Kiang' ('son of the Great River'), the largest river of China, and probably of all Asia, takes this name only in its lowermost course, the entire stream being usually called by the natives only *Kiang* ('the river') or *Ta-Kiang* ('the great river'), while in almost every province it has a special designation. Under the name of Murussu (Chin. 'Mulusu') it rises in the Kuen-lun Mountains, forming the northern wall of Tibet, and forces its way S.E. and S. with numerous windings and cataracts through the wild mountainous plateaux of Tangut and Eastern Tibet till it reaches the Chinese province of Yunnan. Here it passes through a frightful gorge on the frontiers of Yunnan and Sze-chuen, then flows N.E. through the latter province and E. through Hu-pé, entering the great plain of China a little below King-chow, and touching in its winding course the great towns of Han-Yang, Han-kow, and Wu-chang. At Kew-Kiang, in the province of Kiang-Si, it finally turns N.E., and maintains this direction till it has passed Nanking, after which it proceeds E., washing the fortress of Ching-Kiang, and thence S.E., pouring its enormous volume of water into the Chinese Sea, N. of Shanghai. The total length of the Y., including all its windings, is over 3000 miles, and the most recent estimate of its drainage-basin gives it at 1,137,675 sq. miles. The Y. moves tranquilly through the great Chinese plain, safely girdled by its high banks. It is navigable for between 1400 and 1500 miles from its mouth. On account of its central course and the great number of rich provinces through which it winds, it is called the 'girdle of China;' and by its numerous affluents (of which the chief are the Ta-Chung, the Wen, the Kia-ling, and the Han-Kiang from the N.; and the Wu, Yuen, and Kan (through Lake Poyang) from the S.), and its connection with the Imperial Canal, it forms the most important water-way in China, and one of the greatest in the world.

Yani'na. See JANINA.

Yan'kee, at first a slang name for a New-Englander, was extended during the American Revolution to all the insurgents, and in the Civil War was the common designation of Federal soldiers by the Confederates. In England, Y. is applied to natives of the United States generally. Originally a corruption of *English*, or Fr. *Anglais*, by the N. American Indians, it was probably first used by the British soldiers in America in 1775. An American national air, *Yankee Doodle*, is said to have been popular in England in the time of Cromwell, who was ridiculed as 'Nankee Doodle.' Others say it was the original tune of the English song, 'Lydia Locket lost her pocket,' to which the words of *Yankee Doodle* were composed (1775) by a British sergeant.

Yap'ock (*Cheironectes Yapock*), a species of Opossum (q. v.), found chiefly in Brazil and Guiana, and adapted to a semi-aquatic life. The fore feet are webbed as far as the first joint of the fingers, and the hinder feet are wholly webbed. The ears are pointed, and there are cheek-pouches. The average length is about 2 feet, and the tail is long. The colour of the Y. is a fawn-tinted grey, marked with four transverse bands of black on the back. The food consists of fishes, insects, crustaceans, &c.

Yard, the British standard of length, is defined by Act of Parliament, 18 & 19 Vict. c. 72, July 30, 1855, as 'the straight line or distance between the centres of the transverse lines in the two gold plugs in the bronze bar deposited in the office of the Exchequer,' when the temperature is 'at 62° Fahrenheit.' Should this standard be destroyed, as happened at the burning of the Houses of Parliament in 1834, it may be replaced by means of its copies, or, should these fail, it can be restored by pendulum observations. The yard is divided into three feet, and each foot into twelve inches. The statute mile contains 1760 yards.

Yard, in the rigging of a ship, a horizontal spar hung across a mast by 'halyards' or 'lifts,' and sustaining and extending a square sail. It is adjusted to suit the wind by means of 'braces.'

Yarkund', or **Yarkand'**, the chief town of the province of the same name in E. Turkestan or Independent Tartary, 140 miles S.E. of Kashgar. It is a great emporium of trade between China and the W., but it has been repeatedly devastated by the internecine wars which are chronic in Central Asia. The pop. is estimated at 100,000. The bulk of the inhabitants are Mahommedans of the Turki race; and in 1866 it was captured from the Chinese by Yakub Beg, who afterwards entered into a commercial treaty with the British in India, and caravans of traders annually pass to and fro through the valley of Cashmere. A commercial treaty was signed between Yakub Beg and Sir Douglas Forsyth in 1874. The exports are chiefly shawl wool, raw silk, gold, and borax; the imports are piece-goods, metal wares, tea and indigo. In 1875–76 the registered exports from Y. into the Punjaub were valued at £19,000, chiefly *charas*, an intoxicating preparation of hemp; the imports at £9000, chiefly Indian tea. In 1876 an English company sent its goods direct to Y. under European conduct, and Y. merchants annually come down to the Punjaub. The soil of the province, which is watered by the Y. river, a tributary of the Tarim Kul, which flows E. into the lake called Lob Nor, is said to be fertile; the crops are wheat, rice, barley, millets, fruits, and mulberry; and there are large herds of sheep, goats, cattle, and horses. See Sir Douglas Forsyth's *Narrative* of his embassy.

Yar'mouth, capital of Y. county, Nova Scotia, 130 miles S.W. of Halifax, has a good town-hall, several churches, 3 secondary schools, and 2 weekly papers. Shipbuilding and fishing give employment to a pop. of (1871) 5335.

Yar'mouth, Great, a seaport of Norfolk, England, 20½ miles E. of Norwich by rail, stands on a neck of land between the estuary of Braydon Water and the German Ocean, about 2½ miles N. of the mouth of the Yare, a suspension-bridge over which connects it with the suburbs of Southtown and Gorleston. One of the distinguishing features of the ancient town is 145 'rows' or narrow streets, resembling the Edinburgh 'wynds,' which branch at right angles from the four main thoroughfares, and recall the sea-rover days when the townsfolk huddled within fortifications, of which only picturesque fragments of three flint-built towers survive, with trifling remains of the connecting curtains. But the sea-frontage wears all the aspect of a fashionable watering-place, two piers (450 and 753 feet in length) projecting from the fine esplanade, while the river is fringed by spacious and well-planted quays. St. Nicolas (founded 1101; partly restored by Mr. Hakewill (1848), and partly by Mr. Seddon (1864–1870), but still incomplete), is a noble cruciform structure representing every period of Gothic architecture, and the transitions. It is said to be the largest parish church in the kingdom, and has a tower and a spire 168 feet high; later churches are St. George's (1716), St. Peter's (1835), one for the beach-men (1858), another for wherry-men (1860), and a third for the fisher-folk. The public edifices include a town-hall (1716), Assembly and Reading Rooms (1862), the Trinity Corporation Buildings (1868), with an octagonal tower 75 feet high, covered fish-market (1867), Sailors' Home (1860), also a home for smack boys, erected as a memorial to the Rev. J. Walrond (1873), Grammar-School (1863), the Nelson Column (1817) 144 feet high, a theatre, public library, &c.; and new municipal buildings, with quarter and petty sessions courts: a central hall and assembly rooms are now (1879) about to be erected. The harbour was entered in 1878 by 1455 vessels of 181,760 tons, and cleared by 1499 of 186,478 tons; and on December 31, 7120 vessels of 31,126 tons were on its register, besides 1099 fishing-boats manned by 4633 hands. The herring-fishery is Y.'s staple, the 'Y. bloater' being widely famed. In 1877 there were landed here 254,760,000 herrings, a yield more than ten times as large as in any recent season. Other industries are shipbuilding (139 British vessels of 6592 tons during 1874–78), rope, sail, and net making, silk-spinning, and brewing; and there is a considerable trade, the exports (herrings, barley, malt, and ale) amounting in 1877 to £24,095, and the imports (timber, coals, corn, wine, and

brandy) to £403,753. Y. publishes three weekly newspapers, and returned two members till 1867, when it was disfranchised for corrupt practices. Pop. (1871) 41,819. See Nall, *Y. and Lowestoft* (1866); Palmer, *History of Y.* (1856), and *Perlustration of Y.* (3 vols. 1876).

Yarn is any textile fibre prepared for weaving into cloth. Yarns are spun into a great variety of sizes, according to the purposes for which they are intended, and the fact that different standard sizes are adopted in different countries leads to great confusion and seriously impedes international traffic. Many proposals have been made with the view of introducing a uniform standard, but no general agreement has hitherto been arrived at. In Great Britain the numbering of Y. is as follows: cotton and floss or spun silk, No. = number of hanks of 840 yards per lb. Flax and jute, No. = number of 'leas' of 300 yards per lb. Woollen and worsted Y., No. = number of skeins of 560 yards per lb. Raw silk, organzine, and tram are estimated according to French standard in 'deniers,' the No. = weight and grains per hank of 476 metres.

Yar'oslav. See Jaroslav.

Yarr'ow. See Achillæa.

Yarr'ow, an affluent of the Ettrick, rises at Yarrow Cleugh, 1½ miles E. of Loch Skene, flows mainly E. through the Loch of the Lowes and St. Mary's Loch, and joins the Ettrick 2 miles above the town of Selkirk, after a course of 25 miles. This river holds a unique place in Scottish song and legend. The district through which it flows embraces some of the finest scenery of its kind in Scotland; but it is not to this, but to the sad sweet ballad that tells of the despair of love on the 'dowie dens o' Y.,' that it owes its rare romantic interest, and the spell that drew some of their finest poems from Hamilton of Bangour, Logan, and Wordsworth.

Yawl. See Jollyboat.

Yawn'ing, a modification of the act of inspiration, in which the action is intensified and prolonged, while the muscles of the jaws, and, to some extent, those of the larynx as well, are spasmodically affected so as to produce an enlargement of the mouth. Y. is involuntary, and may be excited through the imitative principle by the occurrence of the act in another person.

Yaws, or **Frambœ'sia,** generally considered an acute specific disease, occurs in Guinea, America, Africa, and the West Indies, particularly in Jamaica and Dominica. Y., called also *mycosis* (fungus) and *piaro*, is almost entirely confined to the African races, and was brought to the W. Indies by negro slaves. A report on this disease has been recently published by the Colonial Office from the pen of Dr. Gavin Milroy; and Doctors Fox and Farquhar have recently published, under the sanction of the Secretary of State for India, an account of it in their work *On Certain Endemic Skin Diseases of India*, the first satisfactory description of Y. which has been published. It has been very fully investigated by Dr. Imray of Dominica, and Dr. Bowerbank of Jamaica. Dr. Imray says:—'If Y. are observed as they first make their appearance on the surface, one or more minute whitish or yellowish points or spots will be perceived, not larger than a pin's head. These yellow spots are seen very distinctly on the dark skin of the negro. Gradually the spots enlarge, and begin to project from the surface, retaining for the most part their circular form, and have much the appearance of small globules of yellow pus, and unless carefully examined might be so mistaken. The skin remains unbroken until the Y. attain perhaps the size of a small pea, but the cuticle may give way at any time. Then a yellowish, spongy surface presents itself, from which a thin fœtid fluid oozes, and this spongy body continues to enlarge, and projects considerably from the surface. Y. are usually circular in form, and may be seen in the same patient of all sizes, from scarcely more than a pin's head to a patch of more than one or two inches in diameter, and in every stage of their progress. Generally they are separate, but sometimes in groups close together, small and great. Again, they are met with of an oval form, but more rarely. In other cases they are irregular in shape, and so close together as to make one mass. It frequently happens that one of these tubercles assumes very large proportions, one or two inches in diameter, or even more, projecting from the skin like the other Y., and covered with yellow scabs, receiving in English the name of *mother* Y., and in the French patois, *maman pian.* All the other Y. may entirely disappear, and the mother Y. only remain; and, if neglected, it will degenerate into an intractable ulcer, eating its way into the tissues, and causing extreme and irreparable destruction of the parts around, and be often accompanied by great constitutional irritation and extensive emaciation.

'The eruption generally breaks out on the face, the neck, the upper and lower extremities, the parts of generation, the perinæum, the hips, and about the anus. They are much less frequently observed about the trunk, and are not so often seen on the hairy scalp. They may form on the nostrils where the mucous membrane joins the skin, and here the Y. may assume an elongated form, nearly closing the nostril, and hanging down on to the lip. Near to the mouth they may appear in such numbers and so closely set as to form almost a ring around the mouth. This is especially the case in children. Around the anus also they sometimes coalesce, and form one projecting circular band, an inch and more in breadth. An attack of Y. varies much in severity as regards the size and actual number of Y.'

The usual duration of Y. is from two to four months, under appropriate treatment; or about thirteen months in severe cases; but it may last for years with periods of quiescence. Y. is a communicable disease, and Dr. Imray speaks positively of its being conveyed from person to person by contact, or the absorption of the poison through some abraded surface, though it is not infectious. The poison may be carried from individuals by flies. The period of incubation is thought to be from three to ten weeks.

Regarding the treatment of Y., Dr. Imray says:—'In the early stage it is customary first to wash the patient, then to encourage the full development of the eruption by the exhibition of sulphur and supertartrate of potash for six or eight days. In the next place, mercury is to be administered in conjunction with decoction of sarsa, or sassafras, or mezereum, in the form of *tisanes*, to which great virtues are attributed. The mercury is to be dropped directly signs of its action on the gums show themselves. Tonics should be conjoined with mercurials in the case of weak persons. Occasionally aperients are also needed. The diet should be good and unstimulating. As regards local applications, Dr. Imray advises a carbolic-acid solution, or weak nitrate of mercury ointment. The natives apply the boiled and beaten-up leaves of the physic nut, *Jatropha curcos;* the juice of the sour orange, the *Janipha manihot;* or the flowers of sulphur dusted over the part. Mercury, according to Dr. Bowerbank, is the active ingredient in all the Y. specifics used in Jamaica. Iodide of potassium is also efficacious, especially if the disease attacks the mucous membranes. See *Report on Leprosy and Y. in the West Indies*, 1873, printed at H.M. Stationery Office, and issued in 1873; *On Certain Endemic Skin and other Diseases of India and Hot Climates generally*, by Tilbury Fox, M.D., and H. V. Carter, M.D. (Lond. 1876).

Yazoo' River (from an Indian word meaning 'river of death'), a tributary of the Mississippi, United States. It lies throughout its whole extent in the state of Mississippi. The Y. R. proper, formed by the confluence of the Tallahatchie and the Yallobusha, commences below Polckville, and after a deep, slow, tortuous S.W. course of 290 miles enters the Mississippi 12 miles above Vicksburg. It traverses a fertile country, and is throughout navigable. The waters of the Tallahatchie are partly received from the Mississippi itself, and, but for a slight obstruction, steamers from the Mississippi might thus enter the Y. R. at its extreme source, and after traversing its whole length, re-enter the Mississippi at Vicksburg.

Yea'don, a town of the W. Riding of Yorkshire, England, in the Valley of the Aire, 6 miles N.N.E. of Bradford. It has large woollen mills. Pop. (1871) 5246.

Year, a period of time determined by the earth's revolution round the sun, including the four seasons, and usually divided into twelve months. Its value, expressed in mean solar days (see Day), varies somewhat according to the manner in which it is reckoned. Thus the *sidereal* Y., or the interval between the instant at which the earth, sun, and a given star are in a certain relative configuration, and the next instant at which they are in

the same configuration, is 365.25638 mean solar days. The moist yellow surface, streaked with red. This, amongst the *equinoctial* or *tropical* Y., *i.e.*, the interval between the earth's successive returns to a given point on the ecliptic, such as one of the equinoctial points, is only 365.24226 days, somewhat less than the sidereal year because of the annual precession of the equinoxes (see PRECESSION). The *anomalistic* Y. is the time in which a revolution is completed with respect to the apses, and is 365.25971 days, a little longer than the sidereal Y., because of the progressive motion of the apse. Of these the most important from terrestrial considerations is the tropical Y., since it is upon the passage of the sun from the one side to the other of the ecliptic that the phenomenon of the seasons depends. It is therefore also the *civil* Y.; but for convenience it is advisable that the ordinary Y. of reckoning should contain an exact number of days, either 365 or 366. The former would of course be too small and the latter too large; and the error, if suffered to accumulate, would soon make the first day of the Y. occur at all possible seasons. For example, if the length of the civil Y. be taken at 365 days, there would be nearly a day of error in four years, and a whole Y. within 4 centuries. To obviate this, Julius Cæsar, advised by the astronomer Sosigenes, ordered that the civil Y. should every four years have 366 days. This made the Y. exactly equal to 365¼ days, a little over 11 minutes too long, an error which at the time of Pope Gregory XIII. (1582 A.D.) had amounted to ten or eleven days. To correct this, a modification was then introduced, which made the even centuries ordinary years, excepting such as are divisible by 400, which are leap years. According to the Gregorian calendar, then, a Y. is 365·2425 mean solar days, which is greater than the true Y. by nearly 21″, an error which requires nearly 4000 years to amount to a day. See CALENDAR, MONTH, DAY, &c.

Yeast is an organised substance consisting of minute globular or ovoid cells, which under favourable circumstances develop and increase with great rapidity, by new cells budding from the parent cell. The cellular organism belongs to the simple form of life which occupies a middle place between the vegetable and animal kingdoms, although it is generally classed among vegetable bodies, and regarded as a fungoid spawn, to which the name *Saccharomyces cerevisiæ* is given. Y. is the active agent in producing alcoholic fermentation in all saccharine solutions, its growth in any solution containing or capable of producing sugar, causing the sugar acted on to decompose into alcohol and carbonic acid, with some other substances of minor importance. It therefore plays a most important part in industrial economy, as it not only is essential to the production of wine from grape juice and other fruit juices, the manufacture of beer, and in the preparation of distilled spirits, but it is also the agent in producing the panary fermentation whereby ordinary bread is rendered light, porous, and spongy. The Y. organism has been the subject of numerous and most valuable investigations, the latest and greatest of which are those of M. Pasteur, who has demonstrated that alcoholic fermentation is the invariable result of the action of Y. cells on, and their growth in, solutions of sugar, and that when fermentation other than alcoholic ensues, it is due to the action of agents other than ordinary Y. cells, which indeed possess an individual existence as distinct as that of any species of being. This observation is of the utmost practical importance as explaining the various obscure and most troublesome maladies which affect all fermenting liquids, and often lead to serious loss on the part of wine-producers, brewers, and even bakers. M. Pasteur has further indicated a means whereby practically pure Y. cells may be obtained, and thus safe and uniform vinous fermentation secured. The Y. obtained from the surface of fermenting beer-mash is known as barm, and used for starting new fermentation, and for the preparation of bread. Dry or German Y., which forms a considerable article of import and trade, is made by removing the barm from the surface of a fermenting liquid, straining off any liquid portion through a fine sieve, and then pouring the barm into cold water, in which it sinks to form a sediment. The sediment is subsequently collected, placed in a stout bag, and pressed into a doughy mass, with the addition of a proportion of potato starch. For further details see BREAD and BREWING.

Yedd'o (officially *Tokio* or *Tokai*), the capital and the largest city of Japan, situated in a fertile plain watered by a canal from the Tonegawa River, on the E. side of the island of Nipon, and at the head of the Bay of Y., 18 miles N.E. of Yokohama by rail. The town is well built, its straight streets crossing regularly at right angles, and it is next to London the most spacious city in the world, covering a total area of 60 sq. miles, only 28 sq. miles of which, however, are built over, the remainder being covered with intervening gardens and groves, while one-eighth of the whole is occupied by moats and canals. Y. comprises three towns: (1) *Siro*, the central part of the city, or the citadel, and the military quarter, containing the residence of the Mikado, surrounded by a stone wall and a moat; (2) the *Soto-Siro*, joined to the former by more than 30 granite bridges, containing upwards of 3000 palaces, the residences of those nobles of high rank (Daimios and Hattamothos) whose possessions were not sequestrated at the suppression of the feudal system, also the locality of the government buildings, colleges, schools, arsenals, barracks, foundries, steam-mills, and factories; (3) the *Midsi* or merchant city, densely populated, and closely built with brick and stone buildings in the European style. At the N. and S. ends of the city are the cemeteries, filled with tombs and temples. In the city are 741 Shinto shrines, 2179 Buddhist temples, and 4 Christian churches. The Government estimates for 1875-76 include an item of £64,000 advanced for brick houses in Y. The city has been repeatedly destroyed by earthquakes, most recently in November 1855, and, accordingly, the houses consist at most of two stories, the upper chambers being used only as store-rooms. Many of the houses are built of bamboo-wood and cement, but, being painted white, they have the appearance of being of stone. The interiors consist of but one chamber, divided into apartments by paper-screens. Everywhere the most scrupulous cleanliness prevails. Fires are very frequent, notwithstanding the extraordinary precautions taken against them. At certain distances at the principal points of the city rise high bell-towers in the form of columns, which are mounted by a series of ladders and provided with great bronze bells, and which command the whole quarter. In almost every house a wooden fire-engine is kept in readiness, and every fifty steps are arranged pyramids of buckets kept constantly filled with water. The old palace of the Mikado was burned down, May 5, 1873, but has been lately rebuilt at a cost of £200,000. Water is abundantly supplied by wooden aqueducts from the Tonegawa, 9 miles distant. For police purposes Y. is divided into six principal and ninety-six smaller districts, with stations connected by telegraph, and a force in uniform of 3500 men. Y. has an imperial university with 100 foreign instructors, and its schools have an aggregate attendance of 60,000 pupils. It has several banks, and 18 newspapers and periodicals; and native capital has established many cotton, woollen, and paper mills driven by steam. Hundreds of horse vehicles and over 20,000 *jin-siki-sha* ('man-power carriages') ply the streets, which in 1872 were first lighted with gas. On the 12th June of the same year the first railway to Yokohama was opened. Its receipts in 1875 were £86,559. Other lines have been projected to connect the capital with Osaka, Hiogo, and Kioto, the last 236 miles distant from Y. It is connected by telegraph with Nagasaki, Hakodadi, and other cities. Y. has no direct foreign trade of any consequence, as its harbour only receives small vessels. All its imports pass through the custom-house of Yokohama (q. v.). In 1877 there were at Y. 468 Europeans and 54 Chinese. Pop. (with the suburbs, 1874) 813,500. Y. was laid out in 1591, when the walls of the present citadel were built. In 1650, in 1854, and again in 1855, it suffered severely from earthquakes. In 1861, British and French legations were established here, but were soon forced to leave, not to return until 1865. In 1862 Y. ceased to be the compulsory residence of the Daimios, and in 1868 it became the residence of the Mikado, when its name was changed to Tokio ('eastern capital'). On January 1, 1869, the port was formally opened to foreign trade, and in the summer of 1871 Y. became the centre of the entire power of the empire. See Sir Rutherford Alcock, *Capital of the Tycoon* (Lond. 1863); Fortune, *Y. and Pekin* (Lond. 1863); and *Pekin, Y., and San Francisco: The Conclusions of a Voyage Round the World*, from the French of the Marquis de Beauvoir, by A. and H. Stephenson (Lond. 1872).

Yell, the second in size of the Shetland Isles (q. v.), and, except Unst, the most northerly of the group, is separated from the Mainland by Yell Sound, and from Unst by Blue Mull Sound. From N. to S. it measures 17 miles, while its extreme breadth

is 7½ miles. Area, 94 sq. miles; pop. (1871) 2732. The E. coast is low and flat, the W. rocky and precipitous, and the surface is hilly, much of it barren moor. Fishing is the chief occupation of the inhabitants.

Yell'ow Berr'ies. See FRENCH BERRIES.

Yell'ow Bird (*Chrysomitris tristis*), a species of Finch inhabiting N. America. It is yellow above, with a black head, wings, and tail. The under parts are of a brown colour. The average length of the Y. B. is 5 inches. It is often domesticated on account of the sweetness of its song. The food consists chiefly of the seeds of plants.

Yell'ow Col'ours. The most important yellow pigment is chrome yellow, a chromate of lead which can be prepared any shade of yellow and orange. Other Y. C. are Naples yellow, a compound oxide of lead and antimony, cadmium yellow, a sulphide of cadmium, Dutch pink, a yellow earthy colour prepared by impregnating an earth with extract of Persian berries, Indian Yellow (q. v.), yellow ochre, an earth coloured with oxide of iron, and orpiment or arsenic yellow, which consists of a sulphide of arsenic.

Yell'ow Fe'ver is 'an infectious continued fever, ushered in with languor, chilliness, and more or less severe lumbar pain and frontal headache, countenance flushed, eyes at first humid, then suffused, and ultimately ferretty, skin imparting a tingling heat to the touch, and, as the second stage advances, gradually acquiring a lemon or greenish-yellow tinge, mind usually disturbed with hallucinations, or more or less violent delirium, restless watchfulness, or, possibly, drowsiness even to extreme coma, epigastric uneasiness, spontaneous vomiting without effort, first of a clear glairy fluid, but subsequently with *coffee-ground* flocculi, or blood itself, often, towards the close, with irrepressible hiccough, and wild shrieking or melancholy wailing, tendency fatal, but the disease generally confers an immunity from subsequent attacks.' The first recorded outbreak of Y. F. occurred in the West Indies in 1647, and since that time it has been recurring at regular intervals in an epidemic form, and gradually extending its range; but it is endemic in certain localities, and notably so in the islands of St. Thomas and St. Domingo. Regarding its *altitudinal* and *horizontal ranges* Dr. Macdonald says,—'It may be very well to assign an altitudinal limit of the spread of Y. F.; and, roughly speaking, this may be estimated at between 2000 and 3000 feet above the level of the sea, but the local conditions of every country seem to determine a range peculiar to itself. Thus the disease has been known at Newcastle, Jamaica, at an elevation of 4000 feet, while in the valley of the Mississippi its highest recorded range is about 600 feet (admitting the fever of Gallipolis to be of the genuine type). Humboldt alludes to the farm of Encero, in Mexico, at an elevation of 3243 feet, as the altitudinal limit of black-vomit. At St. Domingo the encampments of the French in 1792 and of the English in 1796 enjoyed an immunity from the disease, while it was spread far and wide among the troops in the low country. Though the West Indian islands, and the neighbouring coasts of North and South America, may be looked upon as the focal area of Y. F., yet, taking the outlying points at which its occurrence in the epidemic form has been recorded, its geographical range must be regarded as very considerable indeed, *i.e.*, between 97° W. and 2° E. longitude, and between 48° N. and 35° S. latitude. At least for the space of a century and a half, up to the year 1850, the river Amazon, dividing the Brazils from Guiana, limited the extension of Y. F. south of the line; and while the disease was raging at Rio and Bahia, at the close of that epoch, the Montevideans flattered themselves that they were without the geographical limits of the pestilence, until it fell to their turn to sustain its visitation several years later, when the illusion was dispelled. Similar facts may be adduced regarding the extension of the disease along the shores of the Pacific; so that, however well we may be acquainted with its present range, making all due allowance for temperature, we cannot tell what the future may bring forth. In this connection it may be mentioned that a temperature of at least 72° is assumed to be essential to the development of Y. F., though cases exceptional to this rule may now and then happen.'

The phenomena of Y. F. evidently result from the operation of some specific organic poison upon the system through the blood, the poison being eliminated chiefly by the gastro-intestinal mucous membrane when both liver and kidney have been rendered ineffective in bringing about this result. There can be no doubt whatever that Y. F. is a communicable disease, though there is difference of opinion as to whether it is contagious or infectious; or as to whether the specific poison is generated within or without the human body. Hænisch says:—'Y. F. is most probably produced by a living miasm, which has hitherto entirely eluded microscopic demonstration, but the existence of which is argued from very many facts. These seeds of disease, as soon as they become in any way established in a human organism, set up in it that diseased process to which we are accustomed to give the name of Y. F. They are not, however, reproduced in this diseased organism, they do not multiply in it, nor migrate from it to other men; Y. F. is not, then, in this sense, a contagious disease. But its seeds long retain their poisonous nature; they are, under certain circumstances, quite indestructible, and when placed in suitable external conditions are capable of kindling an epidemic even far away from their place of origin.' This seems to be a commonly received opinion by physicians engaged in practice in districts where Y. F. is frequently epidemic. The Surgeon-General of the United States Marine Hospital Service stated, in a circular issued in September 1878, that 'Y. F. patients have been treated in the marine hospitals at St. Louis, Cairo, Louisville, and Cincinnati without communicating the disease, simple precautions having been taken to disinfect the clothing and other effects immediately on receiving the patients. It is a well-known fact that the unacclimatised attendants upon Y. F. patients at the New York Quarantine Station do not contract the disease. Y. F. is transported by *things*, and not by persons considered apart from clothing.' The late Dr. Nott of Mobile, the late Dr. Warren Stone of New Orleans, and Professor Stillé of Pennsylvania, maintain the same doctrine; but the question still remains *sub judice*. The infectious nature of Y. F. is generally admitted by British physicians. Professor Stillé sums up a recent lecture (March 1879) on Y. F. as follows:—'(1.) Y. F. originates nowhere but in the West Indies. (2.) Its morbid poison is conveyed elsewhere in ships and fomites. (3.) Wherever conveyed, a high temperature is essential to its propagation. (4.) A strict quarantine is always efficient in preventing its dissemination. (5.) It is not contagious. (6.) Its essential cause cannot be isolated or defined, but must be assumed to be a specific poison. (7.) This poison in the system acts primarily in two ways, by disintegrating the blood and inflaming the stomach; and that, secondarily, it tends to impair the eliminating functions of the kidneys.' Professor Stillé, however, admits that Y. F. is highly infectious.

The last great epidemic of Y. F. occurred in the United States of America in 1878. The disease was introduced into New Orleans on May 23, 1878, and before July 12th, thirty or forty deaths from it had occurred, the reports of which were at the time suppressed. It broke out in the form of a series of groups of cases, each being connected with some other by personal association or by exposure in the same locality, and from these separate foci the conflagration spread over the whole city. Thence it was carried in the clothing or about the persons of people going from the infected districts. In other instances it was conveyed in such fomites as cotton bagging, or goods of some description, or bedding and blankets. The panic-stricken inhabitants of New Orleans sought refuge in flight, and spread the infection eastward and northward to the Ohio River and beyond it. The epidemic continued till October 1878, and the estimated number of deaths was about 15,000.

In December 1878 a Board of Experts, consisting of twelve medical men and a sanitary engineer, with Surgeon-General Woodworth as President, was appointed by the Health Committees of the Senate and House of Representatives of the Congress of the United States of America to investigate the Y. F. epidemic, and they came to the following conclusions. (1.) Y. F. is a specific disease, due to a specific poison which has not been chemically or microscopically demonstrated, nor in any way made evident to the human senses; it is material and particulate, and endowed with the vital properties of growth and reproduction; the disease is not malarial, and malarial influences do not contribute towards its dissemination or mortality to any greater extent than to other epidemic diseases; a concurrence of local conditions seems to be necessary to the evolution of the disease, but what these are we have no positive knowledge. (2.) Y. F. is a disease of singular local attachments,

often prevailing in a very small section of a city, with remarkable indifference to topographical and social surroundings; whilst atmospheric air is the usual medium by which it is conveyed, it has been in no instance established that the disease has been carried to any considerable distance by atmospheric currents, or by any modes or vehicles of conveyance other than those connected with human traffic and travel; the period of incubation varies from two to five days; the fever is unknown in Asia; the white race is most susceptible to its influence, and furnishes the highest ratio of deaths. (3.) Y. F. is a disease of warm climates and of warm seasons; it is destroyed easily by exposure to air, by frost and by chemical disinfectants, when they can be adequately used; and one attack confers immunity from a second. (4.) The disease was unknown to the inhabitants of the eastern hemisphere until after the discovery of America by Columbus, and the islands of the W. Indies are its home; it has never made its appearance on the great continent of Asia, nor in Australia, nor in any of the islands of the Pacific Ocean, nor on the Pacific coast of the American continent; and outside the W. Indies the disease is an exotic. (5.) The fever has invaded the United States in eighty-eight different years, in seventy-seven of which there is evidence of importation, and in seventy-one of these seventy-seven the evidence points to the W. Indies; that, as a rule, very nearly without exception, Y. F. has always appeared in some of our seaports before it has made its appearance anywhere in the interior of the country; the disease is not indigenous to the United States, and it travels by the lines of human intercourse, no instance of communication having occurred in shorter time than would have sufficed for a man to have made the same journey.

Regarding the *treatment* of Y. F., it may be said that there is no known specific, and it is thus symptomatic; but whatever is to be done should be done quickly, and the earlier a clear diagnosis is formed the better. The fever commences abruptly, and is attended with severe headache, great irritability of the stomach, and vomiting, the vomited matter being first slimy and tasteless, but afterwards black like coffee-grounds. When the sixth day elapses without the occurrence of black vomit or suppression of urine, hopes of recovery may be entertained, but the mortality is usually one in three. On the first invasion of the disease the *pediluvium* may be employed, and warm drinks given to promote perspiration. The bowels, which are usually constipated, should be opened with a purgative; and, if the constipation continues, by enemata. Acetate of ammonia, nitrate of potash, nitrous ether, and the tincture of squills and hyoscyamus may be given, and lime-juice for drink. The irritability of the stomach may be allayed by limewater in combination with milk; or chalk-mixture, as the vomiting frequently depends on the presence of free hydrochloric acid in the stomach. Creosote, hydrocyanic acid, chloroform, or chlorodyne may be used, and when procurable, ice may be swallowed. Morphia may be injected subcutaneously in the epigastric region. Chlorate of potash and tannic acid have been recommended. The strength should be supported by giving, after short intervals, the essence of beef, and digestion will be aided by the administration of pepsine. Stimulants should also be given, champagne in particular when it can be procured. Hænisch suggests that transfusion of blood, after previous blood-letting, might paralyse or modify the injurious operation of the Y. F. miasm. Surgeon-General Woodworth recommends those exposed to the infection of Y. F. to use small doses of quinine, chlorate of potash, and tincture of iron. 'As the poison enters the system through the air-passages, it has been suggested that the nasal passages be bathed frequently with a solution containing quinine, to be applied by means of a nasal spray.' See *Y. F.*, by Dr. Macdonald, in Reynolds' *System of Medicine* (Lond. 1878), *Y. F.*, by Hænisch, in Ziemssen's *Cyclopædia of the Practice of Medicine* (Lond. and New York 1874), *Practical Hygiene*, by Dr. Parkes (Lond. 1878), *Conclusions of the Board of Experts Authorised by Congress to Investigate the Y. F. Epidemic of* 1878 (Wash. 1879), *Y. F., its Origin, Propagation, &c.*, by Professor Stillé, in *Medical Record* (New York, March 1879).

Yell'ow Legs (*Gambetta flavipes*), a *Grallatorial* or Wading bird, allied to the *Scolopacidæ* or Snipes, and found along the eastern coasts of N. America, passing to the north in summer, but returning south in winter. Its average length is 10 inches, and the colour is ashy brown above and white beneath, both surfaces being marked with brown. The legs, as the name indicates, are yellow, the bill is straight, slender, and pointed. The Y. is esteemed as a table bird, especially in autumn, when it is in good condition after its summer feeding.

Yell'ow Hammer or **Yell'ow Bunting** (*Emberiza citrinella*), a species of Bunting (q. v.), common in fields and hedgerows, and attaining a length of 6 or 7 inches. It is of a bright yellow hue, with dark-brown markings, that of the back being mottled with brown. The under parts are a pure, brilliant yellow, and the flanks are brown. The colours of the female are less vivid than those of the male. The song is somewhat plaintive. The nest of the bird is usually found at the roots of hedges buried among the long grass growing in such situations. The female lays five eggs of white colour, marked with brown, and both parents tend the young. In winter the Y. H. becomes very fat, and is then in esteem for the sake of its flesh. The proper name of the bird is 'yellow-ammer,' 'goldammer' being the German form.

Yell'ow Sea', or **Whang-Hai'**, a great gulf of the Pacific Ocean on the N.E. coast of China, bounded on the N. and E. by Corea and Japan, and on the W. by China proper. From N.W. to S.E. its length is 600 miles, while its breadth is often 350. The Gulf of Pe-chi-li forms its upper and inner extremity. Extremely shallow, the Y. S. is gradually silting up. It receives its name from the yellowish mud which forms much of its bottom.

Yell'owstone Riv'er, in the N.W. corner of Wyoming Territory, United States, flows N. from the upper corner of Yellowstone Lake (330 sq. miles in area, 7427 feet above the sea), and after a course of 1300 miles reaches the Missouri, having descended about 7000 feet. In 1872 Congress set apart a tract of land 55 miles by 65 about the sources of the Yellowstone and Missouri rivers as a great national park for the benefit and enjoyment of the people. See UNITED STATES.

Yell'ow Throat (*Trichas Marylandica*), a species of Warblers (q. v.) occurring in N. America. Its length is about 5 inches, and the colour olive-green above, with a yellow breast and throat, the male exhibiting a black band on the forehead as part of its summer plumage. The nest is built on the ground, and the song is musical, but not very strong.

Ye'men (*i.e.*, 'the land to the right of Mecca'), a district in the S.W. of Arabia, bounded on the N. by Hedjas and on the E. by Hadramaut, and measuring about 400 miles in length by about 150 in breadth. At about 30 miles from the coast a range of wooded mountains (rising occasionally to 6000 and 8000 feet) stretches along the whole length of the country. Between this range and the sea stretches the scorchingly hot plain called Tehameh. Further inland the country becomes an elevated plateau. Though destitute of rivers, the whole region is very fertile, and coffee, tobacco, dates, gums, and spices are produced and exported in abundance. There are valuable pearl-fisheries on the coast. The inhabitants are Arabs, but possess many distinctive characteristics, and are supposed to be descended from the ancient Sabæans. The government rests with the different sheiks or tribal chiefs, among whom the Imaun of Sana (q. v.) holds supreme authority. The principal towns in Y. are Sana (q. v.) the capital, Mocha (q. v.), and Hodeda Mareb. Aden (q. v.) is not now within the limits of Y. The *Arabia Felix* of the ancients, Y. was conquered by the Abyssinians (525 A.D.) and Persians (597). In the year 628 it submitted to Mohammed, since the 16th c. has been subject to Turkey, and after the extension of Turkish rule (1871–73) was formed into a vilayet.

Yenika'lé or **Kertch** (formerly of *Kaffa* or *Feodosia*), **Strait of**, the Cimmerian Bosphorus of antiquity, connects the Sea of Azov with the Black Sea. It is 20 miles long, 2 miles wide at its narrowest part, and is much interrupted by shoals.

Yenisse'i, the longest river of Siberia, rises as the Kem to the W. of the Kosso-Kol, S. of the Gurbi Mountains, flows W. as the Ulan ('Great') Kem between the Sayan and Tangnu Mountains, then suddenly breaks northward through the Sayan Mountains, and after a course of 3440 miles falls into the Arctic Ocean. Its breadth varies from 3400 feet to 14 miles, and during the last 140 miles it is so wide as to form an arm of the sea. Its depth varies from 11 to 90 feet. The waters of the Y.

are clear and rich in fish. They are navigated (1878) by four paddle-steamers, of 20 to 60 horse-power, and drawing barges of 64 to 240 tons, and by 13 boats of 40 to 45 tons, besides a number of five- or six-cornered flat-bottomed boxes which convey flour down stream, and are broken up at their destinations. The Y. receives from the right the Upper Tunguska or Angara (the outlet of Lake Baikal), the Irkut, Middle Tunguska, and Lower Tunguska. Nordenskjöld's (q. v.) voyage in the summer of 1875 from Tromsö to the mouth of the Y. opened up a trade by sea with N. Siberia, in which a number of vessels are now (1879) engaged, finding six weeks in summer when the passage to and from the Y. can be made with little difficulty.

Yenisseisk′, a government of E. Siberia, Russia, bounded E. by Yakutsk and Irkutsk, S. by Mongolia, W. by Tomsk and Tobolsk, and N. by the Arctic Ocean. Area, 992,571 sq. miles; pop. (1873) 396,783. The S. part is occupied with the Altai Hills and their offsets. In the Yenissei valley considerable tracts are under tillage, but N. of the town of Y. this is succeeded first by pasturage, then by stretches ever more and more desolate, to the frozen *tundras*. The chief river is the Yenissei (q. v.). Smaller streams are the Taimyr, Katanga, and Anabar, which, like the Yenissei, form great gulfs at their mouths. The gold-washings of Y. occupy 12,000 to 15,000 men and several thousand horses. Of the native tribes, who live by hunting, fishing, and trade in fur, the most are Samoyedes and Tungus. The capital is Krasnoiarsk (q. v.).—**Y.**, a town in the above government, on the river Yenissei, under 58° 27′ N. lat., has 11 churches with gilded cupolas. The trade in flour, sugar, tea, tobacco, and especially schnaps, is mainly dependent upon the gold-washing. There are 157 public-houses and 4 small schnaps-distilleries. Pop. (1878) 6000.

Yeolá, a town in Nassick District, Bombay Presidency, British India, 130 miles N.E. of Bombay. Pop. (1872) 17,461. It has special manufactures of silk and cotton cloth, woven on the hand-loom with elaborate designs, with broad borders of gold or silver thread.

Yeo′man, the '*man* of a *Gau*' (q. v.) or country district (*cf.* Fris. *gæman*, 'villager'), from a designation of a menial servant, became the title of one who had 'free land of forty shillings by the year' (Blackstone), and so ranked next below an esquire.

Yeo′manry, a force of volunteer cavalry in Great Britain consisting of county gentlemen and yeomen. It dates from the great struggle with revolutionary France. The Y. are organised in local troops of from 40 to 100 men, to each of which a drill-sergeant from the regular army is attached. From 4 to 8 troops form a regiment which is entitled to an adjutant; 42 corps of 233 troops, in all numbering about 15,000 men, are now (1879) in existence. Unlike the ordinary volunteer force, the Y. may be called out in aid of the civil power in addition to their being liable for service on invasion of the country by a foreign enemy. They undergo six days' training in each year, when they receive a subsistence allowance of 7s. per day, and 2s. per day for forage, and they must also attend nine drills yearly, when an allowance of 2s. per man and 1s. 4d. per horse is made for each occasion. They must furnish their own horses, but are allowed £2 each per annum for clothing. The constitution of the force is regulated by the Volunteers Act of 1804 and the Y. Regulations of 1864.

Yeo′men of the Guard, or, as they are vulgarly called, **Beefeaters** (q. v.), a company of veteran soldiers, 100 strong, forming on state occasions the body-guard of the sovereign, conjointly with the gentlemen-at-arms. They are officered by a captain (usually a peer), a lieutenant, an ensign, and four exons. The corps was constituted by Henry VII. in 1485, and the old-fashioned uniform worn by them is of the period of his reign.

Yeo′vil, a town of Somerset, England, on the Yeo, 20 miles S.E. of Bridgewater by rail. Among its buildings are the church of St. John, a Perpendicular edifice of the 15th c., the new Trinity church, and 5 Dissenting chapels, also an almshouse and town-hall. The manufacture of gloves is the staple industry. Upwards of 2000 men are employed in the factories, and still more women are engaged sewing in their homes. There are also woollen manufactures, and much butter is produced in the neighbourhood. Pop. (1871) 8527.

Yess′o, or **Jess′o**, an irregular island of Japan, N. of Nipon, 350 miles long by 250 broad. Area, 35,739 sq. miles; pop. (1872) 123,668, mostly Ainos ('hairy men'), who are thought to be the last remnants of the aborigines of Japan, an active, docile race, living by hunting and fishing. A *terra incognita* up to 1862, Y. was thoroughly surveyed during 1871–75. It has a wild, mountainous, volcanic surface, is well wooded, and abounds in bears, deer, and wolves. Coal and sulphur are plentiful, and the fisheries of the rivers and neighbouring waters promise much future wealth. The Japanese are gradually opening up the southern portion, and 190 miles of road have been constructed. Sapporo, the capital, and Hakodate (q. v.), a treaty port, are both in the S.

Yeth′olm, a village of Roxburghshire, Scotland, 7 miles S.E. of Kelso, consists of two parts, Town and Kirk Y., which are linked by a bridge over the little Bowmont. Lying at the foot of the Cheviots and within 1½ miles of the English Border, Kirk Y. has for at least two centuries been famous as the 'Gypsy town.' Its quaint old inn, resembling a Spanish *venta*, was kept by Will Faa, smuggler and Gypsy king (1784–1847); a little above it stands the lowly palace of Queen Esther Faa Blythe, who was crowned 'with many a barbaric ceremony' in 1861. But, in truth, these Gypsies, who numbered (1862) 126, have become so mixed with Irish and the surrounding natives, as to have lost almost every trace of their ancient tongue and their ancient customs. See Borrow's *Romano Lavo-Lil* (Lond. 1874).

Yew (*Taxus*), the type genus of the tribe *Taxineæ* of the natural order *Coniferæ*, and comprising, according to Parlatore, six species (all, however, reduced to forms of *T. baccata* by Hooker). They are slow-growing and long-lived evergreen trees or shrubs, with tough red heartwood, leaves linear, distichous, flowers sessile in the axils of the leaves, generally diœcious, male catkins subglobose, the female flowers consisting of a few imbricate scales enclosing an erect ovule surrounded at the base by a disc which enlarges into a red fleshy cup surrounding the seed. *T. baccata* extends throughout Europe, N. Africa, and in Asia eastward to the Himalaya. It forms a large tree with dense dark-green foliage, is of very slow growth, attaining not uncommonly in England a girth of 25 to 30 feet, with a height sometimes of 50 feet, and specimens exist supposed to be nearly 2000 years old. In India it is recorded 100 feet high, but with girth of 15 feet only. The sapwood is whitish, the heartwood is reddish brown, compact, hard, and heavy. It is strong, elastic, takes a beautiful polish, and is used for all kinds of turnery, for carving, and other purposes which require a firm and elastic wood. Whip-handles are made of the branches, and from time immemorial the Y. has been the principal wood used for bows. The succulent fruit has a sweet mawkish taste, but is not unwholesome. Though goats, rabbits, and sheep eat the leaves without injury, they are poisonous to cattle and horses, and in the human subject have a similar effect to digitalis. The western Y., *T. brevifolia* of N.-W. America, is a stately tree with a beautifully white or slightly yellow wood as close and fine-grained as the European species. The Indians use it for their bows. The allied genus *Torreya* bears the name of stinking Y. on account of the leaves and wood emitting a disagreeable odour when bruised or burned. The timber of *T. taxifolia* and *T. myristica* is heavy and close-grained.

Yezd, chief town of a province of the same name in W. Persia, in a large oasis on the confines of the great desert of Khorasan, 230 miles E.S.E. of Ispahan. The desert surrounds it on the N., E., and S., but on the W. a series of small oases connect that of Y., which is watered by the Mehris, with the more fertile districts E. of Ispahan. Y. is of great importance as a commercial centre, being the crossing-point of several great caravan routes—viz., those from Herat and Meshd, from Ispahan and Shiraz, and from Kirman. It thus becomes an entrepôt for the commerce between India, Turkestan, and Western Asia. Silks, cottons, carpets, felt, velvet, and sugar-candy are manufactured and largely exported. Pop. about 40,000, of whom many are Guebres, or fire-worshippers.

Yg′drasil, in the Northern Mythology (q. v.) the giant ash-tree symbolising the whole universe. It had three roots, one in the world of men, another among the Hrimthurser, the third over Niflheimr, while its branches stretched over the whole world and enveloped the heaven.

Y Moth (*Plusia gamma*), a species of *Lepidopterous* insect, well known in Britain and on the Continent, and derives its name from the presence of a mark on the front wings resembling the letter Y or the Greek gamma (γ). The Y M. is one of the day-flying moths, and its larva, a caterpillar, feeds on the pea, bean, turnip, cabbage, and other vegetables. Occasionally in France the larvæ are very destructive to gardens and crops. The average length of the moth is one inch.

Yo'ga ('junction,' from the same root as the Lat. *jungo*), one of the six schools of Hindu philosophy, upon which is based the practical duty of asceticism. Its one doctrine is the constant and intense concentration of the mind upon the Supreme Being, by which a 'junction' is effected between the individual and the universal spirit. Unnatural postures, suppression of the breath, a hermit life, and forced trances are inculcated as means towards this end. The modern Sivite ascetics, who practise horrible austerities, are commonly known as Yogis. The name of the reputed founder of the school is Patanjali. See *A Contribution towards an Index to the Bibliography of the Indian Philosophical Systems*, by Dr. Hall (Cal. 1859), and Monier Williams' *Indian Wisdom* (Lond. 1875).

Yokoha'ma, the principal seaport and the third city of Japan, on the E. side of the island of Nipon, upon Yeddo Bay, and separated from Kanagawa by Y. Bay, 18 miles S.W. of Yeddo by rail. Its harbour is spacious and supplied with commodious piers, and is the scene of an active foreign and coast trade. The junk transports have now almost entirely disappeared before the superior facilities afforded by small steamers and by the railway to the capital, which has been open since June 12, 1872. Y. is connected by telegraph with the other open ports, as also with the island of Yesso since September 15, 1874. The town is well built and regular, though the houses are almost entirely of wood. Fires are very frequent; the most disastrous of late years occurred in 1873 and in 1874. Y. dates its prosperity from its being opened to foreign trade by the Yeddo Treaty (August 26, 1858), as in 1859 it was still a small fishing village. A great part of the trade which formerly passed through Kanagawa (q. v.) has been transferred to Y., but as the former is still the seat of the foreign consuls, the trade of Y. is included in its returns. The port of Kanagawa was entered in 1877 by 309 vessels of 367,755 tons (151 of 151,641 tons British), and cleared by 302 of 360,285 tons (142 of 143,799 British). The imports amounted to $19,490,485, including cotton manufactures ($1,027,237, woollen wares $2,890,382, and metals $1,157,078); the exports to $15,628,337, including silk ($10,043,413, tea $12,613,188, rice $797,439, and copper $389,765). On December 31, 1877, there were within the district of the British consul at Kanagawa, 185 foreign firms and 2501 foreign residents (1142 Chinese, 570 British, 189 Americans). Pop. of Y. (1872) 61,553.

Yonge, Charlotte Mary, born at Otterbourne, Hampshire, in 1823, earned her popularity by *The Heir of Redclyffe* (1853) and *The Daisy Chain* (1856), two High Church novels, which have reached in 1879 their 23d and 15th editions, and whose profits were mainly devoted to fitting out a missionary schooner for Bishop Selwyn and founding a college at Auckland in New Zealand. Since then Miss Y. has edited the *Monthly Packet*, and published some 60 volumes more of novels, history, biography, and miscellaneous works. Among them are *Landmarks of History* (3 vols. 1852–57), *Heartsease* (1854), *History of Christian Names* (1863), *Dove in the Eagle's Nest* (1866), *Cameos from English History* (3 vols. 1868–76), *Life of Bishop Patteson* (1873), *Pillars of the House* (1873), *My Young Alcides* (1875), *Three Brides* (1876), *Beginnings of Church History* (1877), *The Disturbing Element* (1878), and *Primer of French History* (1878).

Yonk'ers, a town of New York, U. S., on the Hudson, 17 miles N. of New York by rail. It has 14 churches and 3 weekly newspapers. There are three wool hat factories, 4 carpet factories, 3 silk factories, machine factories, &c. The assessed value was in 1875 $20,906,904. Many New York merchants have handsome villas here. Pop. (1875) 18,357.

Yonne, a department of Central France in the basin of the Yonne (q. v.) and its tributary the Serain. Area, 2868 sq. miles; pop. (1876) 359,070. The surface is an undulating and richly-wooded plain, varied with chalk hills and table-lands, and in the S.W. by a considerable range. The soil is very fertile. Wine and corn are the two chief products. Iron is found in abundance; also anthracite, quartz, granite, marble, and good building-stones. There are some foundries, woollen mills, cloth mills, tanneries, lace and paper factories, and iron-works. Auxerre (q. v.) is the capital.—**Y. River** rises in Nivernais, and flows N. and then N.W. through Y. to the Seine, receiving on the left the Nievre, and on the right Eure, Serain, Armançon, and the Vannes. Its total course measures 169 miles, of which 72 are navigable. By the Nivernais canal it is united with the Loire; by the canal of Burgundy, with the Saône and Rhone.

Yoo'sufzye (*Yusufzai*, 'children of Joseph'), a numerous Afghan tribe, on the N.W. frontier of India, occupying about 2000 sq. miles within the British district of Peshawur and also the hills beyond the N. boundary. Their total number is estimated at 246,000, including 73.000 fighting men. Of these 80,000 are British subjects; 800 are serving the Bengal army, and 360 in the Punjaub irregular force. The crops of their territories are wheat, barley, millets, maize, cotton, and mustard-seed. The Y. export iron, cattle, and wool; and their transit trade is considerable. Those within British territory have become good subjects.

York (Lat. *Eboracum*; Old Eng. *Eoforwic*), the capital of Yorkshire and the seat of the Primate of England, ranks second among English cities, and gives its chief magistrate the title of Lord Mayor. It stands in a plain at a point where the three Ridings meet, and where the navigable Ouse receives the Foss, 191 miles N.N.W. of London by the Great Northern Railway, whose fine new station (erected outside the walls in Italian style 1873-77) is the largest in the world, the covered portion measuring 800 by 234 feet. Save for a gap of 500 yards on the eastern side, the ancient walls (kept up at a yearly cost of £150) run wholly round the city, and, having a circuit of 2¾ miles, afford a splendid promenade. With their ten 'bars' and posterns they mainly date from the 14th c., but retain some portions of Agricola's work, and follow for 3000 yards earthworks ascribed to Romanised Britons. Above the red-roofed houses, mingled with trees and gardens, the mighty Minster uplifts its central and two western towers, the one 216, the others 201 feet high, and all three in the same Late Perpendicular style (1404–70). Of Paulinus' Church (627) nothing remains but a few rough stones worked into the richly-channelled pillars of a Norman crypt (1070–1181), which itself is older than any portion of the superstructure—the Early English transept (1215–56), the Decorated nave and chapter-house (1285-1345), the Early Perpendicular Lady chapel and presbytery (1361–73), and the Perpendicular choir (1373-1400). The exterior is characterised by massive grandeur; within one is struck by the singular breadth and unbroken vista of a structure whose dimensions are 486 feet from E. to W., 223½ across the transept, and 104½ across the nave, the height of the latter being 99½, of the choir 102, and of the lantern 180 feet. Carlisle alone can offer a rival to the exquisite tracery of the western, Gloucester to the vast surface of the eastern window, each of them glowing with the original painted glass. The west façade has been pronounced 'more architecturally perfect than that of any other English cathedral;' other beauties of the Minster are its matchless octagonal chapter-house, its lancet 'Five Sisters,' the wealth of its ancient glazing, and its monuments of Archbishop Gray and Greenfield and of eleven more primates. Twice utterly destroyed by fire (741 and 1069), it lost the old wooden roofs of choir and nave, the stalls, and bells in two recent conflagrations, the first occasioned by a mad incendiary (1829), the second by a workman's carelessness. The cost of the two restorations amounted to £88,000; and in 1873–74 £20,000 was expended on the southern transept. Out of 58 ancient churches and chapels 23 survive—All Saints, North Street, with a spire 120 feet high, and rich in old painted glass, as also are St. Martin, St. Saviour, St. Denis, and St. Martin-cum-Gregory; St. Mary the Younger, a blending of many styles, from Primitive Romanesque to Decorated; St. Mary, Castlegate, with a spire of 155 feet; St. Michael-le-Belfre (1545), the church of Guy Faux's baptism, &c. Four modern Anglican churches were built during 1852–75, but the chief addition to the ecclesiastical architecture of Y. is the Roman Catholic pro-cathedral of St. Wilfrid (1864), an elaborate Italian Gothic edifice with a tower 147 feet high. In the grounds of the York-

shire Philosophical Society (established 1822), on the banks of the Ouse, stand the beautiful ruins of the mitred Benedictine abbey of St. Mary (1074). They comprise a 13th c. church and an hospitium (now used as a museum of antiquities); and near them are the Society's building, the Roman 'Multangular Tower,' the ruins of St. Leonard's Hospital (founded by Æthelstan, and rebuilt by Stephen), and the King's Manor (occupied by the Wilberforce school for the blind), which, built from the abbot's house for the Lords President, has memories of Strafford and the two first Stuarts. Here too a Fine Art Exhibition was opened May 7, 1879, whose Permanent Building, in Italian style, is 104 feet long, and contains a concert hall with a fine organ, picture-galleries, &c. Y. Castle, long since converted into the county jail, was thoroughly remodelled at a cost of £203,530 (1821-23), but its ruined 13th-c. Clifford's Tower retains some fragments of the Conqueror's masonry (1068). In the keep, whose site it occupies, 500 Jews slew first the women and children, then themselves (1190). Other noteworthy buildings are a Perpendicular guildhall (1446), the Mansion House (1728), Assembly Room (1736), the Decorated Micklegate (where the heads of Richard of Y. and other rebels were once impaled), and Monkgate, mixed Norman and Decorated, with an almost unique portcullis chamber. To these may be added the numerous medical, charitable, and educational establishments, the last including St. William's College (1460), a grammar-school (1546), and the Royal School of St. Peter (1557). The river trade and industries have lost their ancient importance, but iron-founding, brewing, tanning, and the manufacture of drugs, confectionery, combs, &c., are carried on, and the customs amounted (1877) to £13,179. Y. publishes three weekly newspapers, and returns two members to Parliament. Pop. (1871) 50,761. The ancient settlement of the Brigantes, converted into a Roman station by Agricola (*circa* 79 A.D.), rose to be capital of Roman Britain, and alone among British towns was the Cæsars' dwelling-place, where died Severus (211) and Constantius (306), and whence Constantine the Great went forth to Trier, York's sister imperial city this side the Alps. When from *Eboracum* it had changed to *Eoforwic*, Y. reappears as the Northumbrian capital, seat of the newly-converted Bretwalda, Eadwine of Deira, who here was baptized by the first bishop, Paulinus (627), and began the building of a church of stone. Then came the great Danish invasion (869), the city's alternate capture by Rægnald (923) and Æthelstan (937), lastly the choice of Eadgar the Peaceful to be King of the English (959), whereby the royalty of Northumbria, and so of Y., came to an end. In 1016 it submitted to Cnut; under Eadward the Confessor it witnessed the foundation of Earl Siward's church of St. Olaf, the revolt of the Northumbrians, and their massacre of Tostig's housecarls; in 1066 it received both Harold Hardraga and Harold of England; and in 1069 the sons of Swegen, with Eadgar Ætheling and Earl Cospatric, made the last Danish raid, sailing up the Ouse and putting the Norman garrison to the sword. The Battle of the Standard (1138) saved Y. from the hostile Scots, two of whose kings did homage here to Henry II. In 1298 one out of several parliaments was summoned to Y., where for seven years the Courts of King's Bench and Exchequer continued to sit, and which has been visited by almost every English king. The Wars of the Roses and Pilgrimage of Grace (q. v.) struck grievous blows at York's prosperity, and in 1644 the battle of Marston Moor forced its surrender to the Parliament. See works cited in King's *Northern Cathedrals* (Lond. 1869) and in Dixon and Raine's *Lives of the Archbishops of Y.* (vol. i. Lond. 1863), also Freeman's *Points in Early Northumbrian History* in *Macmillan* (September 1876).

York, a city and township of Pennsylvania, U.S., on Codorus Creek, at the head of Chesapeake Bay, 100 miles W. of Philadelphia by rail. It has 24 churches, a library, academy, granite court-house, 6 banks, 2 daily, 8 weekly, and 2 monthly papers. Iron-foundries, coach-works, whip manufactories, and shoemaking works are the chief industrial establishments. Pop. (1870) 11,003.

York, a river of Virginia, U.S., forming the tidal estuary of the united Pamunkey and Mattapony. From 1 to 3 miles broad, it extends E. for 40 miles to Chesapeake Bay. Y. Spit, at the mouth, is noted for its remarkable lighthouse.—**Yorktown**, 10 miles farther up on the right bank, is notable as the place where Lord Cornwallis surrendered with 8000 men and 235 guns on 19th October 1781. Here also during the Civil War the Confederate General Magruder was blockaded by General M'Clellan, 5th April 1862. The former, however, being reinforced by General Johnstone, was enabled to evacuate the works on 4th May with all his military stores. Pop. (1870) 1000.

York'shire, the largest county of England, lying between 53° 18'-54° 40' N. lat. and 2° 40'-0° 10' E. long., and bounded N.E. and E. by the North Sea, S. by the Humber and the counties of Lincoln, Nottingham, and Derby, S.W. by a corner of Cheshire, W. by Lancashire, N.W. by Westmoreland, and N. by Durham and the mouth of the Tees. Area, 3,882,851 acres; pop. (1871) 2,436,355. Y. has been from very early times divided into three 'Ridings,' viz., the East, North, and West, besides the 'Ainsty' or 'Liberty' of the city of York, and in statistical documents these divisions are treated as distinct counties. The East Riding occupies the S.E. portion of the county, and is separated from the West Riding by the Ouse, while the Derwent valley marks the division between it and the North Riding. It is divided into 6 *wapentakes* (corresponding to the hundreds of other counties), and has an area (including the City of York) of 804,798 acres, and a pop. (1871) of 269,505. The North Riding, occupying the N. portion of the county between the Derwent River and the county of Durham, and separated from the West Riding by the Ouse, the valley of the Ure, and the hills above Wharfdale, is divided into 13 *wapentakes*, and has an area of 1,361,664 acres, and a pop. (1871) of 291,589. The West Riding, occupying the W. and S.W. of the county, has 9 *wapentakes*, an area of 1,716,389 acres, and a pop. (1871) of 1,854,172. The most striking physical feature of Y. is the great central Vale of York, the northern portion of which is traversed chiefly by the Swale, which, rising among the south-eastern offshoots of the Westmoreland hills, flows E. and S.E., ultimately uniting with its sister stream the Ure to form the Ouse, one of the main constituents of the Humber. On both sides of this central vale the country rises, forming on the W. the Pennine range, and on the E. the Hambleton and Cleveland Hills of the North Riding and the Wolds of the East Riding. Between the Cleveland Hills and the Wolds lies the region known as the Marishes, a tolerably level district forming the valley of the Derwent, which flows S.W. to the Ouse. The Wolds seldom exceed 600 feet in elevation, and are much divided by deep winding valleys, while to the S.E. they are succeeded by the flat Holderness district, whose low exposed coast trending N.W. from Spurn Point to Bridlington Quay offers a marked contrast to the precipitous cliffs which in great part form the coast line to the N. of Flamborough Head. The western portion of the North Riding, bordering on the lofty Westmoreland moors, is much wilder than the eastern portion, which rarely exceeds 1400 feet in elevation. The chief heights are Shunner Fell (2346), High Seat (2328), Wild Boar Fell (2325), Rogan's Seat (2204), and Nine Standards (2153). Further S., in the N.W. corner of West Riding, rise the peaks of Ingleborough (2361), Pen-y-ghent (2231), Great Whernside (2414), Dent Crag (2253), &c., from whose eastern flanks flow the Nidd, Wharfe, and Aire, tributaries of the Ouse. The Calder, a feeder of the Aire, and the Don, have their sources on the southern watershed of the South Y. moors, which continue the Pennine range towards Derbyshire. The geology of Y. is very varied. In the W. small portions of Silurian and Old Red occasionally crop up, but over the whole district to the W. and S.W. of the Vale of York the Carboniferous system has a prodigious development. The limestones and shales which form the mountain masses in the N.W. of the county are succeeded towards the S.E. by Millstone Grit, which extending S. along the Y. border-land separates the coalfields of Lancashire from those of Y. and Derbyshire. To the E. of these is a comparatively narrow strip of red marl and magnesian limestone, which runs N. through the Vale of York, closing the Palæozoic succession. In concentric arcs from near York to the mouth of the Tees are arranged the Bunter and Keuper Sandstones of the New Red and the Lias Clays and Marlstones, on which rest the Oolitic formations of the Hambleton and Cleveland Hills. The Lias also skirts round the N.E. coast, and trends S.S.E. towards the Humber in a narrow strip, which is bounded on the E. by the Cretaceous formations of the Wold Hills. The Holderness district, and a considerable extent of country just above where the Y. water system combines to form the Humber, consist of alluvium deposits. The Cleveland Hills are rich in Oolitic iron ore;

the Mountain Limestone of the North Riding yields valuable lead deposits; while towards the S. lie the famous coal districts of Leeds, Wakefield, Sheffield, &c. With such a variety of geological structure there must exist considerable diversity in the climate and soils of diffeient localities as well as in the natural mineral products. The eastern portion has a cold and bleak climate, and is suitable for agriculture only in the more sheltered districts. The Vale of York is generally mild and temperate. The extensive levels in the S. are damp and foggy, but in the more elevated western regions the climate is salubrious, though heavy rains and tempestuous weather prevail. In the East Riding the principal industries are the agricultural. Horses and cattle are largely bred, and wheat and potatoes extensively grown. In 1878 it had under cultivation 672,208 acres, of which 278,320 acres were under corn crops, 108,346 acres green crops, 86,780 acres grass under rotation, 175,880 acres permanent pasture, 1717 acres under flax (chiefly at Patrington); while the stock consisted of 40,103 horses, 80,019 cattle, 508,326 sheep, and 53,130 pigs. At Beverley are agricultural iron-works and tanneries, at Hull extensive shipbuilding, linseed-crushing, oil-refining, and sail-making. The North Riding is principally agricultural in its lower half. In 1878, of its area there were under cultivation 839,888 acres, of which 220,463 acres were under corn crops, 77,247 acres green crops, 74,732 acres grasses under rotation, 436,931 acres permanent pasture; while its stock included 40,874 horses, 149,141 cattle, 697,872 sheep, and 53,771 pigs. In the Cleveland district there are more than 50 mines, employing 7000 miners, which yielded in 1876 5,614,322 tons of iron ore, valued at £1,694,918. For pig and manufactured iron there were, in 1878, 97 furnaces, 694 puddling-furnaces, and 37 rolling-mills. In 1877, 75 furnaces in operation produced 1,374,582 tons of pig-iron. Shipbuilding is carried on at Middlesborough, South Stockton, and Whitby, where alum and jet are also produced. Within the West Riding, in 1878, there were under cultivation 1,181,377 acres, 237,541 acres of which were under corn crops, 93,185 acres green crops, 89,470 acres grasses under rotation, 738,798 acres permanent pasture; while the farm stock consisted of 53,792 horses, 238,108 cattle, 742,431 sheep, and 75,776 pigs. Within it were (1878) 431 collieries, which yielded 15,952,400 tons of coal, 5 Bessemer steel-works, 290 puddling-mills and 40 blast-furnaces, of which the 30 in operation yielded 229,027 tons of pig-iron. Its various and enormous industries are thus localised: coal-working at Barnsley, Leeds, Wakefield, Rotherham, and Sheffield; iron at Leeds, Sheffield, Rotherham, Bradford, and Wakefield; steel at Sheffield and Rotherham; cutlery of all kinds at Sheffield; cotton-spinning at Bradford, Skipton, Settle, Halifax, and Hebden Bridge; worsted at Bradford, Keighley, Halifax, and Wakefield; alpaca at Bradford and Saltaire; woollens at Bradford, Leeds, Halifax, Huddersfield, Wakefield, Dewsbury, and Batley; flax at Leeds and Gildersome; carpets, rugs, blankets, army clothes, and shoddy at Dewsbury, Batley, and Heckmondwike; glass at Castleford and Knottingley; washing-machines at Keighley, and the growing of liquorice at Pontefract. In 1874 the total number of factories for textile fabrics in Y. was 1865, with 8,572,594 spindles and 115,387 looms, the number of hands employed being 222,026. The worsted manufacture alone employed 114,386 hands, 2,312,447 spindles, and 65,789 looms. In 1876, 23 mines yielded 4198 tons of lead ore, 2969 tons of lead, and 8850 ounces of silver. The great abundance of coal and iron—the 'natural commodities' of the district; the peculiar formation of the country, yielding abundant 'water privileges;' and, lastly, the character of the inhabitants, 'sleath-hounds in pursuit of money,' industrious and intelligent beyond the average of Englishmen, have combined to bring Y. to her present high state of prosperity. No part of England of equal extent with Y. contains so many sites and buildings of historic interest. It is sufficient to mention Northallerton, the scene of the 'Battle of the Standard' (1138); Wakefield, of that between Queen Margaret and the Duke of York (1460); Marston Moor, near Tadcaster, where Cromwell's Ironsides first broke the cavalry of Prince Rupert (1644); 'Merry Barnysdale,' near Doncaster, one of the favourite haunts of Robin Hood; and Bolton Castle, the prison for some time of Mary Stuart. Early British remains are numerous in the Cleveland Moors, and Roman at York, Aldborough, Catterick Bridge, Bowes, and Malton. The most interesting buildings are the Cathedral at York; the ruins of Kirkstall, Selby, Roche, Fountains, Byland, Rievaulx, and Whitby abbeys; Bolton and Knaresborough priories; and the ancient castles of Conisborough, Cawood, Knaresborough, Pontefract, Richmond, Middleham, Helmsley, Wressle, and Clifford's Tower at York. See G. Phillips Bevan, *Tourist's Guide to the West Riding of Y.* (Lond. 1877) and his *Tourist's Guide to the East and North Ridings of Y.* (Lond. 1878); and Hughes, *Geography of Y.* (Lond. 1878).

Yor'uba, or **Yarr'iba**, a country of W. Africa, lying between the kingdoms of Dahomey, Benin, and Gando. Its northern portion, which is subject to Fulah Mohammedans, is open and well cultivated, resembling a great garden. To this region there succeeds, on the S., an undulating, wooded country, which in turn merges into the dense belt of primeval forests which, as on the Gold Coast, separates the coast district from the interior. The coast natives are pagans of a debased type, but are improving under the efforts of missionaries. The total pop. of the country is estimated at about 3,000,000, and several of the towns are of large size. The chief are Abeokuta (q. v.), Ilori (60,000), Oyo, and Ibadan. The last is a walled town 18 miles in circumference, and with a pop. of 150,000. Palm-oil, cotton, and ivory are the staple products of the country, whose foreign trade is carried on chiefly through the British colony of Lagos (q. v.).

Yosem'ité Valley, a remarkable granite region in the centre of California, U.S., 150 miles E. by S. of San Francisco. It runs N. and S. midway between the E. and W. bases of the Sierra Nevada, here 70 miles broad, and is itself level, 6 miles long, from ½ to 1 mile broad, and depressed about 1 mile below the surrounding country. The Merced, joined through deep cañons by the Tenaya Fork and the Ililhouette, winds through the valley. On its N. side projects the granite mass El Capitan (3300 feet high), and on the opposite side stand the Cathedral Rocks, with the beautiful Bridal Veil Falls, which descend in a vertical sheet (630 feet), then falling in a series of cascades 270 feet lower. The Y. Creek Fall, also on the N. side of the valley, consists of a vertical fall of 1500 feet, then a descent in cascades of 626 feet, and a final plunge of 400 feet. Also noteworthy are the Vernal and Nevada Falls (400 and 600 feet) on the Merced River, and the Half-Dome Rock towering 4737 feet above the valley. The Y. V. was discovered in 1851. In 1864 it was given by Congress to the State of California 'for public use, resort, and recreation.'

Youghal (Ir. Gael. *eóchaill*, the 'yew wood'), a seaport of Cork, province of Munster, Ireland, at the mouth of the Blackwater, 27 miles E. of Cork by rail. There is an Episcopal church (partly dating from 1464), a Roman Catholic church, convent, hospital, &c. Myrtle Grove, the house of Sir Walter Raleigh, is still well preserved. Y. has a good harbour, a considerable trade in agricultural produce, and extensive fisheries. In 1878 there entered 321 vessels of 26,109 tons, and cleared 320 of 25,505, and on 31st December there were 30 sailing ships of 3703 tons registered as belonging to the port, besides 51 fishing-boats. In 1877 the value of the imports was £5980 (£15,627 in 1873). Y. returns one member to Parliament. Pop. (1871) 6039. Some of the old 'yews' that once covered the slope on which the town stands still remain. See Joyce's *Irish Names and Places* (vol. i. 1869).

Young, Arthur, born at Bradfield, Suffolk, September 7, 1741, son of the rector of the parish, was educated at Lavenham school, and in 1758 apprenticed to a wine-merchant at Lynn. Disliking the business, he made various essays in literature, and in 1759 he succeeded his father in the management of a small farm. This farm he left for a larger in Essex, the lease of which he was afterwards glad to get rid of at a loss. In 1768 he began his agricultural publications with *A Six Weeks' Tour through the Southern Counties*, and this popular work was followed by *A Six Months' Tour through the North of England* (1771, 4 vols.). Of the same period are his *Farmer's Tour through the East of England* (1770–71, 4 vols.) and several lesser performances. In 1784 the first of forty-five volumes of the *Annals of Agriculture* appeared, and in 1787 he began a tour in France, which resulted in his most widely read book, *Travels during the Years 1787–90* (Dublin 1793). This thorough piece of work is not only the accepted authority on French agriculture of the time, but furnishes stores of valuable information regarding the social ferment preceding the Revolution. Y.'s other works are *The Expediency of a Free Exportation of Corn* (1769), *The Farmer's*

Guide in Hiring and Stocking Farms (1770), *Rural Economy* (1770), *A Course of Experimental Agriculture* (1770), *The Farmer's Letters to the People of England* (1771), *Proposals for Numbering the People* (1771), *Political Arithmetic* (1774; 2d pt. 1779), *Tour in Ireland* (1780), *The Question of Scarcity plainly stated* (1800), *Essay on Manners* (1804), *Advantages from the Board of Agriculture* (1809), *Inquiry into the Progressive Value of Money* (1812), *Inquiry into the Rise of Prices in Europe* (1815). Some of these have been translated into Russ, and many into French (*Le Cultivateur Anglais*, 18 vols. Par. 1800-1). In 1789 Y. became secretary of the Board of Agriculture. He died at Bradfield, April 12, 1820.

Young, Brigham, the founder of the Mormon settlement in Utah, and for many years the almost absolute ruler of the sect, was born at Whitingham, Vermont, 1st June 1801. His father was a farmer, and he himself learned the trade of a painter and glazier. Early in life he joined the Baptists, but when about the age of thirty was converted to Mormonism, and openly joined the sect at Kirkland, Ohio, in 1832. In 1835 he was ordained an elder and sent forth among the twelve apostles, the New England States being the district assigned to him. Here he is said to have been very successful in his proselytising labours. On the death of Joseph Smith in 1844 he was unanimously chosen President and Prophet, though he had three competitors for the office, one of whom, Sidney Rigdon, he soon afterwards excommunicated. On the forcible expulsion of the sect from Nauvoo (see MORMONISM) he led them through toils and dangers, which nothing but the most admirable energy could have conquered, over the plains and table-lands to the splendid valley in the heart of the Rocky Mountains, where, between the Wasatches and the Great Salt Lake, he founded (July 1847) the present Salt Lake City. His immediate followers forming a nucleus, others poured into 'the Promised Land,' and in 1849 an attempt was made to organise a State, to be called the State of Deseret, that being the official name given by the Mormons to the district. The United States Government refused to sanction the new State, but Utah was organised as a Territory, and Y. appointed Governor for four years. The appointment of a 'Gentile' governor in 1854 led to serious troubles, as Y. and the other Mormons refused to recognise his authority, and it was not until a force of 2500 troops was sent out in 1857 that the United States Government could enforce its forms upon the turbulent sectaries. Y. was the founder of polygamy as an institution, and was among the first to practise it. In 1852 he promulgated the 'celestial law of marriage,' which he declared to have been revealed to Joseph Smith nine years before. A large party, among whom were Smith's wife and sons, in the Church opposed the innovation, and declared the revelation to be a forgery, but Y.'s influence carried the day. He himself had from fifteen to eighteen actual wives, besides numerous spiritual wives who were formally 'sealed' to him. He was twice indicted for polygamy, but each time the case fell through. His fifteenth wife sued for a divorce in 1875. The barbarous Mountain-Meadow Massacre of 1858 was brought to the notice of the law in 1875. In it a train of 136 emigrants, who had in some way come into collision with the Mormon settlers, was practically exterminated, only a few children being allowed to escape. The court exonerated Y. from complicity in the affair, though the suspicion was never satisfactorily cleared away, but 'Bishop' Lee, a leading Mormon, was condemned to death in 1876, and shot in March 1877. On the 29th of August in the same year Y. died, at the age of seventy-six, leaving 7 widows and 44 children. He was a man of undoubted ability, strength of character, and shrewdness; but even if we make allowance for the peculiarity of his opinions, seems to have had little principle, and to have been swayed strongly by a rather sordid ambition.

Young, Charles Mayne, born January 10, 1777, was the son of a London surgeon eminent in his profession, but brutal to his family. During a visit to an uncle at Copenhagen, Charles so captivated the king that the monarch offered to educate and provide for him if he became a naturalised subject. This offer being declined, he was educated at Eton and the Merchant Tailors' School. After a short experience in a mercantile house, he went on the stage at Liverpool as Douglas in 1798. Next year he was engaged to 'lead' at Manchester. In 1804 he played lovers' parts in Liverpool with Miss Grimani, whom he married in that city, March 9, 1805. This lovely and estimable wife died in the following year. Charles Y. made his first appearance in London as Hamlet; and amid the tumultuous applause accorded to his performance the only hiss was that of his malignant father. Thenceforth he rivalled Kemble—some say, imitating him too much. His stately style, of what we call the Classical, though it is a highly artificial type, contrasted so well with Edmund Kean's that the two often played alternately in the same parts with much pecuniary gain. Up to 1829 he enjoyed uninterrupted favour on the stage and in society. In that year he was tempted to play in America by an offer of £12,000 for ten months. He declined the proposal, however, and at the age of fifty-three retired from his profession with a competency of £60,000. He died at Southwick, near Brighton, June 28, 1856. See *Life of Charles Mayne Y., by his Son, the Rev. Julian Y.* (2d ed. 1871).

Young, Edward, an English poet, only son of Edward Young, rector of Upham, Hampshire, was born at the rectory, June 1681. He was educated at Winchester and at New College, Oxford, where he obtained a fellowship of All Souls in 1708. In 1719 he took his degree as doctor of civil laws. Already he was noted for some genius and a lack of common-sense that often brought ridicule upon him. Report says that when he was composing he would shut up his windows and sit all day by lamp-light, surrounded by skulls and instruments of death. His first poetical essay was an inconsiderable *Epistle to the Right Honourable George Lansdowne* (1712). Next year he prefixed some verses to Addison's *Cato*, and published *The Last Day* and *The Force of Religion*. In Swift's *Rhapsody on Poetry* occur two lines which insinuate that at this time Y. was a pensioned writer on the Court side. On the death of the Queen (1714) he published a panegyric that equally included the new monarch, George I. From part of a letter of Y.'s to Richardson it has been supposed that the poet was once in Ireland, and probably his visit was made in the company of Lord Wharton in 1717. Two years later he wrote *Busiris*, an ambitious tragedy in the artificial French manner. It contains, amid much ranting nonsense, passages of true poetic beauty, and its style hit the humour of the day at Drury Lane. His *Paraphrase on Part of the Book of Job*, which dilates and therefore weakens the original, and a poetical letter on Addison's death, belong to this period. In 1721 a tragedy called *Revenge* followed *Busiris*, and was dedicated to Y.'s most generous benefactor, the Duke of Wharton. Its lofty imagery, its sustained passion, and its minute depiction of guilt, place this tragedy far above its predecessor. Y.'s Satires next appeared under the title of *The Universal Passion* (1725-28), and brought him £3000. The *Satires*, particularly that on women, are full of acute reflections; but Swift was right in wishing that they could have been more angry or more merry. Next to these comes the *Instalment* (1726), an absurd effusion addressed to Sir Robert Walpole; and the new king, who encouraged the navy in a royal speech, was welcomed in an *Ode to Ocean* (1728). In 1728, Y., having entered holy orders, was appointed chaplain to George II.; and his tragedy of *The Brothers*, then under rehearsal, was withdrawn. In the same year he published in prose an *Estimate of Human Life*, and a sermon on Charles the Martyr, entitled *An Apology for Princes*. In 1730 he produced *Imperium Pelagi*, a naval lyric, and obtained the living of Welwyn, in Hertfordshire. Next year he married a widow, Lady Elizabeth Lee, daughter of the Earl of Lichfield. A *Sea Piece* was followed in 1734 by *The Foreign Address*. Both are poor appeals to the taste of sailors. Y.'s great work, *Night Thoughts*, was published in parts from 1742 to 1744. 'The title of my poem,' he writes, 'is not affected; for I never compose but at night, except sometimes when I am on horseback.' Warton says that Y. wrote this sombre poem in opposition to the earthly philosophy of Pope's *Essay on Man*. Its gloomy theology, its many profound reflections, and its imagery, often false but sometimes sublime, together produce an effect of grand solemnity; nevertheless the feeling of its reader is such as he would experience at a gorgeous religious celebration, of the hollowness of which he was convinced. The author wrote *Reflexions on the Public Situation* in 1745, and in 1754 *Centaur not Fabulous*, a series of letters on fashion. In 1759 appeared a prose letter on Original Composition, and shortly before his death he printed a poem on Resignation. He died at Welwyn, April 9, 1765. That Y. had a poetical genius can no more be denied than that he led a life of refinement in society; but such are his bombastic tendencies as a

poet, and such were his petty, time-serving characteristics as a man, that posterity grudges him his due meed of praise. See Mitford's Life, prefixed to his Aldine edition of Y. (2 vols. 1844).

Young, The Right Hon. George, a distinguished Scotch lawyer and politician, eldest son of Alexander Y., of Rosefield, in the county of Kirkcudbright, was born in 1819, educated at Dumfries and Edinburgh, passed advocate in 1840, and soon won a high position at the Scotch bar. During 1862-66 and 1868-69 he held the office of Solicitor-general. In 1869 he was appointed Lord Advocate, and signalised his tenure of office by an Education Act (1872), which for the first time in the history of the nation made primary education universal and compulsory. Y. sat in Parliament for the Wigtown Boroughs from 1865 to 1874, when he was defeated at the general election in February, but was immediately after created a Lord of Session, and one of the Lords of Justiciary in Scotland. His judicial career has been characterised by a brusque vigour, and a surprising celerity in the despatch of legal business.

Young, Thomas, M.D., a celebrated natural philosopher, was born at Milverton, Somersetshire, June 13, 1773. After completing a general and comprehensive education, and acting for some years as private tutor, he removed to London in 1792 to study medicine. He continued his studies at Edinburgh (1794), Göttingen (1795), and Emmanuel College, Cambridge (1797-99). His doctor's degree he obtained in 1807. Meanwhile, in 1800 he had settled in London with the design of becoming a medical practitioner. Having been left a considerable fortune by his uncle, Dr. Brocklesby, he did not push his practice, and had ample leisure for his favourite literary and scientific pursuits. Already in 1799 he had communicated a paper on experiments on sound and light to the Royal Society; and later papers on the theory of light and colours were selected by the council for the Bakerian Lectures. In 1801 he was elected professor of natural philosophy at the Royal Institution, but resigned after two years. His lectures there form the substance of his *Course of Lectures on Natural Philosophy and Mechanical Arts* (1807), a new edition of which, with references and notes by the late Professor Kelland of Edinburgh, was published in 1845. In these lectures physical and mechanical principles are discussed with great originality and power; and the one upon the interference of light has coupled the author's name for ever with that of Fresnel (see UNDULATORY THEORY OF LIGHT). In 1809-10 Y. lectured on medical science at Middlesex Hospital, and in 1811 became one of the physicians of St. George's Hospital, a post which he held till his death. In 1816 he was secretary to the commission for considering the standards of weights and measures, and in 1818 became secretary to the Board of Longitude, ultimately, on the dissolution of that body, taking sole charge of the *Nautical Almanac*. In 1827 he was elected one of the eight foreign associates of the French Academy of Sciences. He died May 10, 1829. Y.'s contributions to the *Philosophical Transactions*, and other scientific and literary publications, were collected and published under the title of *Miscellaneous Works of the late T. Y., M.D. F.R.S., &c.* (3 vols. 1855), of which the first two, including his scientific memoirs, were edited by Peacock; the last, comprising the hieroglyphical essays and correspondence, by Leitch. See *Memoirs of the Life of Thomas Y.* (Lond. 1831), and Peacock's *Life of Thomas Y.* (Lond. 1855).

Y'pres, or **Y'pern**, an old and, until lately, strongly fortified town of Belgium, capital of the province of W. Flanders, on the Yperle, 55 miles by rail S.W. of Bruges, with which, as well as with Ostend and Nieupoort, it is also connected by a canal. Two splendid edifices are the Gothic cathedral of St. Martin, dating from the 13th c., one of the finest churches in Belgium, containing the grave of Bishop Jansen; and the stately town-hall (formerly a cloth-hall) in the great market-place, extending 462 feet by 50 feet, with a fine clock-tower and spire in the middle, and forty-four statues along the front. It was built 1200-1304, and was restored in 1860. Y. has a college, a public library, a picture-gallery, a museum of antiquities, and several hospitals. Its only important industry now is lace-making. Pop. (1874) 15,515. Y. originally sprung up about a fortress built by Baldwin III., Count of Flanders, in 960. In 1388, Philip the Bold, Duke of Burgundy, enlarged the town and surrounded it with walls. It had then 4000 looms and a population of 200,000, and was one of the greatest towns in the Low Countries. It was fortified by Louis XIV. in 1688, and has since suffered several sieges. See M. Alphonse Vandenpeereboom's *Ypriana* (vol. i. 1878), which consists of curious notices, studies, and documents of the city in old times.

Ypsilan'ti, a Fanariot family claiming descent from the Comneni. Its most conspicuous members are (1) **Alexander Y.**, born 1725, a dragoman of the Porte, hospodar of Wallachia from 1774 to 1782, and again in 1790. He was carried prisoner to Brünn in 1792. Released, he returned to Constantinople, propounded a scheme for the fusion of the Greek and Turkish people, but having incurred the suspicion of the Porte was executed in 1805.—(2) **Constantine Y.**, his son, born in 1760 at Constantinople, early planned the freedom of Greece. His scheme was prematurely discovered, and he fled to Vienna. Pardoned by the Sultan, he was hospodar of Moldavia from 1799 till 1805, when he went to Russia, but returned to Bucharest with 20,000 men, again bent on freeing Greece. But the peace of Tilsit interrupting his plans he returned to Russia, and died at Kiev, 28th July 1816.—(3) **Alexander Y.**, eldest son of the preceding, born at Constantinople, 12th December 1792, followed his father to Russia, entered the army, and served with distinction in various campaigns. In March 1821 he entered Moldavia, and raised the standard of revolt among the Roumanians. Russia, however, frowned on his enterprise; the natives were apathetic, and he was defeated by the Turks at Dragaschan, near Galatz, 19th June 1821. He fled to Austria, and was interned at Munkacs in Hungary. He died at Vienna, 31st January 1828.—(4) **Dimitrios**, brother of the preceding, born 25th December 1793, served in the Russian army, and in 1821 went to the Morea, where he played a brilliant part in the struggle. But though a brave soldier and a successful general, as his victory at Tripolitza and his splendid defence of Argos show, his influence was constantly undermined by the 'native' party, who never forgot that he was a Fanariot, and therefore half a foreigner. In 1827, however, he was made commander-in-chief of the Greek army, but the unhandsome treatment he received from the Government of Capo d'Istria compelled him to resign his post, 1st January 1830. He then withdrew from public affairs, and died at Nauplia, 16th August 1832.

Yss'el, or **Ijss'el**, the name of several rivers in the Netherlands. The **Nieuw-Y.**, one of the principal arms of the Rhine, leaves that river below Arnheim, flows N.E. for 16 miles to Doesburg, where it receives the **Oude-Y.** from Westphalia, then N.E., N., and N.W. through Gelderland and Overyssel, past Zutphen and Deventer, receiving the Borkel and Schip-Beek, emptying at Kampen by many arms into the Zuider Zee, and forming a constantly widening delta. It is one of the five main arms of the Rhine, is 320 feet broad at Zutphen, 764 at Kampen, and is 90 miles in length. The **Neder-Y.**, an arm of the Leck, which leaves that stream at Vianen, flows W. through Utrecht, at Oudewater enters S. Holland and flows S.W. past Gouda to join the Maas, forming at its mouth the island of Ysselmonde.

Ystad', a seaport of Sweden, on the extreme S. coast, 55 miles E.S.E. of Copenhagen, and 85 N.N.E. of Stralsund. It has two churches, and manufactures of tobacco, chicory, sugar, soap, cloth, and leather. Y. has a good harbour, is in regular steamboat communication with the chief Baltic ports, and is connected with the S. Swedish Railway by a branch line opened in 1866. There is considerable trade, chiefly in corn (1½ million cubic feet exported in 1874). Pop. (1876) 6663.

Ytt'rium, a rare metal existing in combination and invariably associated with corresponding compounds of erbium, cerium, lanthanum, &c., in gadolinite, yttrocerite, and other of the rarer minerals found chiefly in Sweden and Norway. By a succession of chemical operations Y. and erbium are at length separated together in the form of nitrates; and further separation of the Y. requires a tedious process of fractional crystallisation, the erbium salt being the less soluble, and crystallising first. Metallic Y., containing some erbium, was obtained by Berzelius as a blackish grey powder; but metallic erbium has never been isolated even thus far. *Yttria*, the oxide of Y., has the composition YO, and is a soft whitish powder, which when ignited glows with a pure white light yielding a continuous spectrum crossed by bright

bands. A similar spectrum is given by ignited erbia (EbO), which burns with an intense green light. Solutions of erbium salts give absorption spectra, whose dark bands correspond to the bright lines of the erbia emission spectrum; solutions of Y. salts are colourless and exhibit no absorption spectra.

Yucatan′, a state of the Mexican Confederation, occupying the greater part of the peninsula of Y., has an area of 29,567 sq. miles, and a pop. (1875) of 422,365, of whom five-sixths are pure Indians. The coasts are low, girdled with sandbanks, and unbroken on the N. and W. except by the Laguna de Terminos, but possessing some good bays on the E. In the interior there is a want of water. The climate is hot, but not unhealthy. Maize, rice, tobacco, sugar-cane, coffee, cotton, and indigo are grown; tropical fruits abound; but the great wealth of the land lies in its valuable forests, including most of the dyewoods employed in European industries, and most kinds of wood required for artistic work and fine domestic furniture. Cattle, except swine, are not numerous. The honey and wax of the Y. bees are very highly esteemed. The chief harbours are Campeachy (q. v.), Sisal, Carmen, and Bacalar. The capital is Merida (q.v.). Y. contains numerous remains of a vanished civilisation. Of its ruins of great buildings (called by the Indians *xlapatlı*, 'old walls') the most celebrated are near Uxmal, to the S.W. of Merida. See Cogolludo, *La Historia de Y.* (Madr. 1687; new ed. Campeachy and Merida 1842–45); Norman, *Rambles in Y.* (New York 1844); Stephens, *Incidents of Travel in Central America, Chiapas, and Y.* (new ed. Lond. 1854).

Yucc′a, the botanical name for a genus of *Liliaceæ*, popularly called Adam's Needle. The number of species is about 12, chiefly found in subtropical N. America. Some are of an arborescent habit, producing a crown of linear-lanceolate, more or less rigid leaves, from the centre of which arises an erect panicle of showy, whitish, bell-shaped flowers. Most of the species are hardy in Britain, and *Y. gloriosa* and *Y. filamentosa* are commonly grown as ornamental garden plants. From the Y. leaves, when treated like hemp and flax, a strong fibre suitable for manufacture into cloth or cordage is obtainable, and the macerated stems deposit a feculent matter which yields starch.

Yucca filamentosa.

Yule, the old name for Christmas, still used in Scotland and N. England. It is the same as the Old Norse *Jól* (the festival of the winter solstice, Goth. *jiuleis*, Old Eng. *geól*, *geóhol*, Dan. and Swed. *jul*), which was called after the burning *wheel* that symbolised the circle of the year. The Greenlanders of the present day have a feast at the winter solstice to rejoice at the return of the sun, and Wormius (*Fast. Dan.* lib. i.) tells us that in his time the Icelanders dated the beginning of their year from Y. Some consider Y. almost certainly identical with *gule* in the phrase 'gule of August' (the first day of August), both being derived from the Celtic *wyl* or *gywl*, 'a holiday.' On the eve of Y. our ancestors were wont to light up candles of an uncommon size, and lay a log of wood on the fire, called a 'Y.-log' or 'Christmas Block,' to turn night into day. This custom still survives in the N. of England. In 1684 Herrick tells in his *Hesperides* how the Y.-log of the new Christmas was wont to be lighted 'with last year's brand,' and already in the same year its 'blazes' are condemned by Warmstrey as 'foolish and vaine; and not countenanced by the Church.' See CHRISTMAS; also Atkinson's *Glossary of the Cleveland Dialect*, p. 588 (1868), Grimm's *Deutsche Mythologie*, Brand's *Popular Antiquities* (re-edited by W. Carew Hazlitt, Lond. 1863).

Yunnan, the most S.W. province of the Chinese Empire, has lately been attracting much attention as a channel of trade from Burmah. It lies among the mountains N. from Independent Burmah, and S. of the windings of the Ta-Kiang or Great River. A large portion of the inhabitants are Mohammedans, called Panthays (q. v.) by the Burmese, and of uncertain origin. In 1855 they rebelled against the exactions of the Chinese viceroy, and being assisted by the hill tribes on the frontier, succeeded in establishing an independent government. But in 1871 the enormous resources of the Chinese empire proved successful, and the Panthays found their own principle of extermination turned against themselves. Y. is now entirely restored to Chinese rule. The export and transit trade in 1854 was valued at half a million sterling, and is now again about the same. Y. is known to be rich in gold, silver, lead, iron, copper, tin, mercury, arsenic, and gypsum. The Indian Government have twice tried to open a trade route. In 1868, Colonel Sladen proceeded as far as Momien, but the Panthay rebellion was then at its height. Again in 1875, Colonel Browne advanced with an armed escort from Burmah, but the Expedition was stopped by the sad murder at Manwyne of Mr. Margary, who had just marched through the whole of China alone and unhurt. In 1877 Lieutenant Gill followed the same route, and his example has since been emulated by a Scotch missionary. See *The Journey of A. R. Margary from Shanghae to Bhamo and back to Manwyne* (Lond. 1876).

Yunx. See WRYNECK.

Yu′thia (*Ayodhya*), the former capital of Siam, 40 miles N. of Bangkok, is almost encircled by the Méinan, whose fisheries furnish the town its principal employment. The German Mandelslohe in the 15th, and Portuguese Mendez Pinto in the 16th c., described the marvels of this 'Venice of the East;' but in 1768 it was razed to the ground by the king of Ava, and of its famous structures there only remains the 'Golden Mountain,' a neighbouring pyramid 400 feet high, with a gilded colossal statue of Buddha. The modern town is the summer residence of many Bangkok merchants, and has an estimated pop. of 40,000, including many Chinese and Burmese.

Y′vetot, a small town of France, department of Seine-Inférieure, 21 miles W.N.W. of Rouen by rail, with dyeing, manufactures of silks, cotton, linen, ticking, fustian, and velvet, and an export trade in corn. Pop. (1876) 8444. Y., with a small surrounding district, formed formerly a sovereign principality, popularly termed the 'Kingdom of Y.' The royal title was apparently first assumed by the lords of Y. in the 14th c., and was confirmed by Louis XI. in the 15th c., though tradition points to its origin in a grant of the Frankish king, Chlotar I., as an expiation for the murder at Soissons (534) of Walther de Y. In 1681 the French Parliament divested the territory of its sovereignty, but declared it a free commonwealth, whose lords subscribed themselves 'Princes d'Y.,' and whose inhabitants were exempted from taxes, an immunity which remained till the Revolution. Beranger's song, *Le Roi d'Y.*, is well known. See Duputel, *Le Royaume d'Y.* (Rouen 1835).

Z.

The twenty-sixth and last letter of the English alphabet, occupying the same position as in Latin. The Semitic Zain and the Greek Zeta had a much earlier place. It is properly a double consonant compounded of S and D, but has acquired the pronunciation of the hard terminal S (q. v.). Examples of its interchanges are—Zeus, Diespiter, and Jupiter; zealot and jealous; Gr. *zugon* = Lat. *jugum*, Eng. 'yoke.' At the beginning of words it generally indicates a Greek origin. In a certain class of English derivatives from the Greek ending in 'ize,' and in words formed on the analogy of such derivatives, modern orthography substitutes S. for Z.

Zaan'dam, or **Saar'dam**, a town of the Netherlands, in the province of North Holland, at the confluence of the Zaan with the Y., 4 miles N.W. of Amsterdam. It is divided by the Zaan into East and West Z., and is so intersected by canals that many houses with their gardens form little islands. Z. has several churches, manufactures paper, colours, starch, tobacco, and glue, and carries on shipbuilding and fishing. With the products of its corn, oil, and saw mills, it carries on a considerable trade with the Baltic, White, and Black Seas. Of the famous sixty docks of Z. in the 17th c. most are now closed. At Z. Peter the Great (q. v.) learnt shipbuilding as a common artisan. The house he lived in is still preserved, and bears a stone tablet inscribed *Petro Magno Alexander* (1814). Z. was the starting-point of the Dutch Greenland fishery, now wholly closed. Pop. (1875) 12,392.

Zab'ern, the name of three German towns, (1.) **Z.** or **Elsass-Zabern** (French, Saverne), a town of Elsass, Germany, on the Zorn, 27 miles N.W. of Strassburg by rail. A Gothic Hauptkirche of the 15th c., a castle built in 1667, but now a barrack, and a museum with a collection of local antiquities, are the principal buildings. The Rhine and Maine Canal passes through the town. Tanneries, potteries, and woollen-mills are the chief industrial establishments, and there is considerable timber trade. Z. stands at the mouth of the Z.-Pass, leading across the Vosges Mountains. Pop. (1875) 6201. The Roman *Tabernæ*, this town still contains traces of Roman occupation. It was long an ecclesiastical city belonging to the bishops of Metz, and an episcopal palace occupied the site of its present castle. Always a German town, though held for a time by France, it receded to Germany in 1871, and the castle, formerly occupied by the widows of members of the Legion of Honour, was employed as a barrack. See Fischer's *Geschichte der Stadt Z.* (Zab. 1874). (2.) **Brog-Zabern**, a town of Rhine Bavaria, on the Erlenbach, 8 miles S. of Landau by rail. Pop. 2000. (3.) **Rhein-Zabern**, a town of Bavaria, on the Erlenbach, 4 miles E. of Berg-Z. The Austrians were defeated here by the French 29th July 1793. Pop. 1800.

Zacate'cas, capital of the province of Z., Mexico, 350 miles N.W. of Mexico. It has several fine churches, a college with a library of 10,000 vols., mint, and bazaar. Situated 7741 feet above sea-level, Z. is literally built on silver, and the whole country teems with veins of silver ore, little worked. Pop. (1875) 16,000.—**Z.**, the province (area, 26,833 sq. miles; pop. 397,945), consists chiefly of a desert plateau, rich in metals.

Zachari'as, originally a Syrian monk, succeeded Gregory III. as pope, 741, and occupied the papal throne till 752. By his favourable reply to the famous inquiry of Pippin the Short (q. v.) he laid that monarch under an obligation to the Papacy which he fully repaid by twice saving Rome from the Lombards (q. v.).

Zadonsk', a town of Voronej, Russia, on the Don, 50 miles N. of Voronej. It has some trade and manufactures, and a remarkable cloister. Pop. 7200.

Zafaran'-Bo'li, a town of Anatolia, Asiatic Turkey, on the Chati-su, 190 miles N E. of Scutari. It has 5 mosques, a church, baths, khans, &c. The trade in saffron, here very extensive, has given the place its name. Pop. 15,000.

Zaffre. See COBALT.

Zähr'ingen, the house from which the present grand-ducal family of Baden takes its origin. The name is derived from the ruined castle of Z., in a village of the same name 2 miles N. of Freiburg in Baden. The first founders of the family were from the 8th to the 10th c. Counts of Breisgau, but the authenticated history of the house really begins with Bertold I., 'the Bearded,' who became Duke in 1050, was much esteemed by the Emperor Heinrich III., and received from him the reversion of the duchy of Swabia. He was, however, passed over in 1057 by Agnes, the widow of Heinrich III, in favour of Rudolf of Rheinfelden, and received in 1061 as compensation the duchy of Kärnthen with the march of Verona. He became reconciled with Rudolf in 1070, and fought by his side at Melrichstadt, August 7, 1078. When he saw from Limburg the devastation of his lands by Heinrich IV. he became insane, and died soon after—November 8, 1078. His elder son, Hermann, had died in 1074, leaving a son, Hermann II., who married Judith of Baden, and from whom the present house of Baden is directly descended. The younger son of Bertold 'the Bearded,' Bertold II., Duke of Z. (died 1111), inherited the dominions of his father-in-law, Rudolf of Swabia, and was followed by Bertold III. (fell at Molsheim, 3d March 1122), the founder of Freiburg. His brother and successor Konrad, who founded Münster, was made in 1127 by the Emperor Lothar, 'Rektor' of Burgundy, where his son Bertold IV. (died 1186) and his grandson Bertold V., the founder of Bern (1191), received rich possessions. As Bertold V. died childless (February 18, 1218), his dominions fell to the nearest heirs, the Dukes of Teck, who sprang from a brother of Bertold IV., and the elder Baden line. His Swabian possessions fell to his elder sister Agnes, the wife of the Graf von Urach, and his Swiss lands mostly to his younger sister Anna, wife of the Graf von Kiburg. The remainder, including the towns Zürich, Bern, Solothurn, and Offenburg, fell by testament to the Emperor. See Leichtlen, *Die Zähringer* (Freib. 1831); Vierordt, *Badische Geschichte im Mittelalter* (Tüb. 1865); and Cohn, *Stammtafeln zur Geschichte der Deutschen Staaten* (Brunsw. 1871).

Zaire, a name given to the great African river Congo in part of its lower course. As the important discoveries of Mr. H. M. Stanley regarding this river have been made known since the article CONGO was published, they may be noted here. Mr. Stanley descended the river from Nyangwé, in 4° 25′ S. lat., where it is called the Lualaba, almost to its mouth, the journey extending from 5th November 1876 to 11th August 1877. The identity of the Lualaba with the Congo being thus established, the river is found to have its origin in Lake Bangweolo (q. v.), whence it issues as the Luapula, and flows into Lake Moero, on emerging from which it is called the Lualaba. Frequent cataracts bar its channel, though the stream is 2000 yards broad, until in 2° N. lat., the river, which had hitherto flowed N., turns N.W., subsequently W., and finally S.W., its width increasing to from 5 to 10 miles, except in occasional gorges, while its bosom

is studded with great numbers of islands. About 400 miles from the sea there commences a series of sixty-two cataracts, by which the stream descends 585 feet in 180 miles, and below these are the Yellala Falls (see CONGO). The affluents of the Congo are of great size, especially on the left or S. bank, the chief of these being the Rumani, Sankorra, Kassai, and Kwango. The Kassai rivals the main stream itself in volume, and their waters do not commingle for 130 miles. On the right bank the chief tributaries are the Aruwimi (supposed to be the Welle of Schweinfurth), Mangola, and Mpaha. From the point where it emerges from Lake Bangweolo the total length of the Congo is estimated at about 2350 miles. It flows through a rich and thickly-peopled country, but the natives in many parts are extremely hostile, and some of them are cannibals. Missionaries have already begun to labour amongst them. Mr. Stanley proposes to change the name Congo to Livingstone, in honour of the great explorer. See H. M. Stanley's *Through the Dark Continent* (Lond. 1878).

Za'ma, or **Zama Regia**, a fortified city of ancient Numidia, 300 miles S.W. of Carthage. On 19th October, 202 B.C., it was the scene of a great battle, in which Hannibal was totally defeated by Scipio Africanus. This result was chiefly due to the great superiority of the Roman army in cavalry, under Lælius and the Numidian King Masinissa. Even the possession of 80 elephants by the Carthaginians did not make up for the lack of cavalry, and they were routed with a loss of 20,000 men, including all the veteran troops, Hannibal himself only escaping by flight. The Roman loss was 2000. This battle ended the Second Punic War, and practically settled the fate of Carthage. Z. is now called Zouarin, or Zowareen, and is an insignificant place. See Bosworth Smith's *Carthage and the Carthaginians* (Lond. 1878).

Zambe'si, or **Zambe'se**, the largest river disemboguing on the eastern side of Africa, and probably the fourth largest stream on that continent. Though it had been known by report for many centuries, and though its mouths had been in the possession of the Portuguese for fully 250 years, scarcely anything definite was known regarding the Z. prior to Dr. Livingstone's journeys in 1852 and succeeding years, and even yet its upper course remains unexplored. The Z. is supposed to be formed mainly by the confluence of three streams, viz.:—(1) The Lungebungo, which rises in the Mossamba Mountains, which form the watershed between the Z. system, the rivers flowing W. through Angola to the Atlantic, and those flowing N. to join the Congo. (2) The Leeba, which issues from Lake Dilolo, about 12° S. lat., 17° 40' E. long. (3) The Leeambye, which is believed to be the main stream, and which is supposed to rise in Cazembe's country about 70 miles S.W. of Lake Bangweolo (q. v.). This river flows S.W. to its confluence with the Leeba, then S., and finally in two great curves with an easterly direction, entering the Indian Ocean between 18°-19° S. lat., after a course estimated at 1200 miles, during which it drains an area of probably 600,000 sq. miles. The name Leeambye is retained as far as the confluence of the Chobe, which enters on the S. in 25° E. long., below which, to the commencement of its delta, the river is called the Z. The country through which the upper Z. flows is mainly a plateau from 3000 to 4000 feet above the sea-level, and depressed towards the centre. The river descends from this plateau by a gigantic crack in its basaltic rim, forming, a few miles below the confluence of the Chobe, the Victoria Falls, called by the natives Mosioatunya, *i.e.*, 'smoke sounds here.' The river, here 1860 yards broad, falls 310 feet perpendicularly into the crack mentioned, which is only 80 yards broad, and has a remarkable zigzag course. For 30 miles the river is confined between precipitous rocks, and forms in this part of its course the falls of Moamba, which, grand though they are, appear insignificant in comparison with the Victoria Falls. 460 miles lower down are the rapids of Kebrabasa, where the river runs in a deep rocky groove from 40 to 60 yards wide. In the rainy season the perpendicular rise of the water in this gorge is 80 feet. Below these rapids, from a point 35 miles above the Portuguese settlement of Tete (q. v.), or 355 miles from the sea, the Z. is navigable, though its navigation is difficult on account of the number of islands and sandbanks with which its channel is studded. In the dry season its average depth in this portion of its course is from 5 to 15 feet, and in flood-time from 15 to 30 feet, with a width varying from one to four miles. At its mouth the Z. has formed a delta in the shape of an equilateral triangle, with sides 80 miles long. Through this delta, which is a swampy, malarious region, the Z. discharges by four mouths, of which the Luabo is the deepest. All have dangerous bars at their entrances. The chief tributaries of the Z. on its left bank are the Kafue, Loangwa, and Shire (q. v.); and on the right bank the Chobe. The Z. forms a general, though not invariable, boundary-line between the pastoral races of Kaffir origin and the agricultural Negro peoples. The Makololo, a brown-skinned Bechuana tribe, occupy the central basin of the Z., and their capital, Linyanti, is situated on the Chobe. They hold in subjection the aboriginal inhabitants, who are called Makalaka, and are more numerous than their conquerors. Adjoining the Makololo kingdom on the east, and occupying the watershed between the Z. and the Limpopo, are the Matebele, a warlike Zulu tribe formerly ruled by the celebrated King Moselikatse. Fifty years ago they extended their conquests as far as the N.W. shore of Lake Nyassa, where they are known by the name of Mazitu or Mavitu. The coast tribes are of Negro origin. With the aid of steamers of light draught, one of which began running on the Shire and Lower Z. at the end of 1878, a large trade is likely to arise, the Z. valley abounding in land of the richest kind, well adapted to the growth of all tropical crops. Good coal is found over a very large area, and gold and silver are obtained near Tete and Senna, while the quantity of ivory exported is very great. The slave trade and Portuguese misrule are the chief hindrances to the development of this rich and vast region. See Livingstone's *Travels and Missionary Researches in South Africa* (Lond. 1857); *Narrative of an Expedition to the Z. and its Tributaries* (Lond. 1865); and Mohr's *Nach den Viktoriafällen des Z.* (2 vols. Leip. 1875; Eng. trans. Lond. 1876).

Za'mia, a genus belonging to the natural order *Cycadaceæ* (q. v.). It consists of arborescent plants resembling small palm-trees, with simple cylindrical stems, bearing at the summit a crown of thick pinnated leaves, and producing flowers in separate male and female cones. Z. is represented in tropical America, the W. Indies, and S. E. Africa. In S. Africa, where the natives use the central part of the stem of *Z. cycadis* for food, the name *Caffer-brood* is common among the colonists for the genus. In the Bahamas, the starchy matter from the stems of *Z. tenuis* and *Z. furfuracea* is made into a kind of arrowroot.

Zamios'trobus, a genus of fossil fruits from Mesozoic and Tertiary rocks. They are generally believed to be the cones of fossil Zamias. The Cycads, of which *Zamia spiralis* of Australia is a familiar example, have also been associated with Z.

Zami'tes, the name given to a genus of fossil Cycads, the remains of which occur in strata of Mesozoic age. Allied genera are *Podozamites* and *Pterophyllum*.

Zamo'ra, an old and decayed town of Spain, capital of a province of the same name, on the right bank of the Douro, which is here crossed by a splendid bridge, 55¾ miles W.N.W. of Medina del Campo by rail. Within the town, which is surrounded with high but dilapidated walls, are 22 churches, of which the finest are the Gothic cathedral, with its massive square tower and round Norman arches, and La Magdalena (12th c.), a church of the Templars. Z. manufactures woollens and linens, and has a large trade in wine and fruit. Pop. 11,469.

Zamorin, or **Tamurin** ('lord'), the hereditary title of the Hindu Rajah of Calicut, the most powerful of the native chiefs on the Malabar or W. coast of India with whom the Portuguese came into contact during the 16th c. After the defeat of Hyder Ali, the Z. acknowledged the supremacy of the E. India Company, and agreed to pay tribute. About the year 1800 he ceased to exercise independent jurisdiction; but his descendant, who still retains the title of Z., continues to live at Calicut.

Zamosc', a fortified town of Russian Poland, government of Lublin, on the Wieprz, 50 miles S.E. of the town of Lublin. It was laid out in 1588 in the Italian style by Jan Zamojski, and all its houses have arcades. Its fine castle, the four churches, the arsenal, and the town-house are the chief buildings. Pop. 6781.

Zamouse' (*Bos brachyceros*), a species of *Bovidæ* or Oxen occurring in W. Africa, and named the *bush cow* at Sierra Leone. The ears are specially developed, and a dewlap is absent. The colour is a pale brown; the horns curve outwards and then upwards and inwards, and have sharp tips; the hair is thin, and has a tendency to grow erect.

Zanes'ville, a city of Ohio, U.S., on the Muskingum, 59 miles E. of Columbus by rail. It has 26 churches, 19 schools, 1 daily and 5 weekly newspapers. There are glass-works, machine-shops, carriage-factories, rolling-mills, &c. Z. has water-works of unusual excellence. Pop. (1870) 10,011; estimated (1878) 20,000.

Zan'te, the ancient *Zakynthos*, one of the Ionian Islands, lies in the Ionian Sea, 9 miles W. of the N. part of the Morea and 7 miles S. of Cephalonia. It is 18½ miles long, has an area of 116½ sq. miles, and a pop. (1870) of 44,557. In the S.E. irregular rocky masses stretch down to the sea inclosing the beautiful bay of Chieri; the interior is more level, and is in a high state of cultivation. The beautiful scenery and pleasant climate of Z. have gained for it the name *Il fiore di Levante* ('the flower of the Levant'). The chief products of Z. are currants, which it yearly exports to the value of £480,000, oil, wine, melons, cotton, and silk, and of its woods are the olive, mulberry, and myrtle. The Zantiotes are mostly Greeks, with about 2000 Jews and some Turks, while the chief citizens speak Italian. Z. is much subject to earthquakes.—**Z.**, the capital, picturesquely situated on a bay in the E. of the island, is built all round its harbour (protected by a mole), and its houses, alternating with gardens, rise like an amphitheatre upwards of 100 feet to a wooded hill, on whose summit is the citadel built by the Venetians. The houses are well built, many of them furnished with ornamented arcades and minaret-like towers. Z. is the seat of a Greek archbishop and a Catholic bishop, and has several churches (the finest being the church of the Phæneromeni and that of St. Dionysius), chapels, and hospitals, a theatre, an exchange, and an arsenal, and in its market-place a colossal bronze statue of the Lord High Commissioner Maitland. There are considerable shipping and trade, and manufactures of cottons, hair-carpets, silks, linens, gold and silver ware, soap, and leather. The total value of its imports in 1877 was £171,648, and exports (chiefly currants and olive oil) £214,827. Pop. (1870) 17,516. *Zakynthos* (originally *Hyrie*) was peopled by Achæans from the Peloponnesus, and, according to Homer, belonged to Odysseus. After the fall of Athens, to which it had been subject, it adopted an aristocratic constitution. It then fell successively to the Romans, to the Eastern Empire, to Naples in the 13th c., and in the 14th to Venice, whose it remained till 1797, sharing thenceforth the fortunes of the Ionian Isles.

Zanzibar', or **Zanguebar** ('coast of the blacks'), a territory on the E. coast of Africa, including several islands of considerable size, and a strip of the mainland along the coast from 0° 10' to 10° 42' S. lat., or between Somali Land and the Portuguese territory of Mozambique, a distance of 1100 miles. The inland boundary of this strip is undefined, and on many parts even of the coast the Sultan of Zanzibar's authority is scarcely even nominal. The climate of the mainland is very hot, moist, and unhealthy for Europeans. The vegetation is rich, and tropical produce of all kinds might be grown in abundance. As yet, however, ivory, gum-copal, indiarubber, beeswax, hides, and orchella weed are the chief products of this undeveloped region, which has not yet recovered from the blighting effects of the slave-trade, which is still surreptitiously carried on to a considerable extent, though abolished by treaty on 20th June 1873. The chief towns or trading-posts are Bagamoyo, Kilwa, Mombasa, Malindi, and Lamo. The island possessions of the Sultan of Z. are as yet much the most important part of his dominions, and among them the chief are the islands of Z., Pemba, and Mafia, the area of which is 630, 227, and 200 sq. miles respectively. The first of these is about 25 miles distant from the mainland, is of coral formation, flat, and nowhere exceeds 300 feet in height. It possesses a rich soil, which, aided by a rainfall averaging 200 inches per annum, and a careful system of cultivation, yields plentiful crops; nevertheless, its capabilities of production are still far from being fully turned to account. The chief articles of produce are rice, millet, cloves, sesamum, oranges, cocoanuts, and the sugar-cane. The scenery of the island is of a charming description, beautiful green lanes traversing it in every direction; while the climate is much milder and healthier than that of the mainland.—**Z.**, the capital of the territory (called by the natives Ungŭja), is situated on the western shore of the island of the same name, and has a good harbour, with an extensive and growing trade, carried on chiefly with Britain, India, the United States, and France. The town is irregularly built, and the sultan's palace, a low coral edifice in a mixed Arabic and Italian style, is almost the only noteworthy building it contains. Arabs constitute the ruling class, while natives of India both here and throughout the territory of Z., almost monopolise both the retail and foreign trade. Their numbers were estimated at about 6000 in 1874, and are steadily increasing. Suaheli blacks constitute the bulk of the native population, and in addition there are Wakhadim (the aborigines of Z.), and a mixed population from Madagascar, the Comoro Islands, &c., with Gallas and Somalis in the northern districts on the mainland. The pop. of the town of Z. is estimated at 80,000, and that of the island at 380,000. No estimate can be formed of the pop. of the mainland possessions. Z. has been an Arab settlement since 924 A.D., and for several centuries formed a republic, governed by elders elected by the people. In 1503 it became tributary to Portugal, whose authority, never very well maintained, was finally shaken off in 1735. From 1784 to 1854 it formed part of the possessions of the Imaum of Muscat. On the division of these at the death of one of the Imaums in the year last mentioned, Z. and its dependencies became an independent kingdom, governed by a Seyyid, or 'lord,' commonly called the Sultan. The present Seyyid, Barghash bin Sa'eed, who succeeded to the throne on 7th October 1870, visited England in 1875. See *Z., City, Island, and Coast*, by Captain R. F. Burton (Lond. 1872), and Blue Books.

Za'ra, an Austrian seaport and the capital of Dalmatia, lies on the Adriatic, 129 miles S.S.E. of Triest. Its promontory is separated from the mainland by an artificial channel, and till 1873 was defended by strong fortifications, pierced by two gates, of which the Porta Marina is 'a Roman arch under a Venetian mask.' Of eight surviving out of 30 churches the chief are the Duomo of St. Anastasia (1285), a vast Romanesque basilica, with exquisite cinque-cento stalls and an unfinished campanile; the triapsidal St. Chrysogonus (1407) and St. Simeon's, with a gorgeous shrine, both of these also Romanesque basilicas; St. Mary's, Renaissance itself, but retaining a noble campanile (1105); and lastly, the desecrated, domed round church of St. Donatus, called by tradition a temple of Juno, but not described as such by Constantine Porphyrogenitus (911–59). The interest of Z. lies mainly in the churches, but two Roman columns may also be noticed, besides the former palace of the priors (now the governor's residence), the episcopal palace, and a public library of 20,000 volumes. The preparation of maraschino (200,000 bottles of which are exported yearly), glass-making, and fishing are the leading industries, and in 1876 the roomy, secure harbour was entered and cleared by 1173 vessels of 184,000 tons. Pop. (1869), without the garrison, 8014. Having under the first Augustus become a Roman colony with the name of *Jadera* (changed by the 10th c. to *Diodora*), Z. about 1000 passed from the Eastern Empire to Venice, and thenceforward its history consists of conquests and reconquests between the Island Republic and the Croatian and Hungarian kings; the crowning episode being its capture from Lewis of Hungary by the united arms of Venice and the Frank crusaders (1202). In 1409 the Venetians bought it of Ladislaus of Hungary for 100,000 ducats, and in 1797 it passed with Venice to Austria, which, after resigning it to France (1809), recovered it by a week's bombardment (1813). See Freeman's *Historical and Architectural Sketches* (Lond. 1876).

Ze'a. See MAIZE.

Ze'a (anc. *Ceos*), an island of the Grecian Archipelago, included in the nomarchy of the Cyclades, lies 13 miles to the E. of Cape Colonna. Area 34 sq. miles; pop. (1870) 8687. Oval in shape, it attains an elevation of 1863 feet in Mount St. Elias, and is of great fertility, its products including wine, honey, figs, and silk. The capital, Z. (anc. *Iulis*), stands 3 miles inland from its port, Limani, and among other fragments of antiquity retains a colossal rock-hewn lion, and had a pop. (1870) of 3789. Birthplace of the lyrists Simonides and Bacchylides, Z. belonged in the Middle Ages to the Duchy of Naxia, with which it fell into the hands of the Turks (1566), and was held by them down to the erection of the modern kingdom of Greece.

Ze'a, Francisco Antonio, born at Medellin in Colombia, 20th October 1770, for sharing in a revolutionary movement was imprisoned at Cadiz, Spain (1797–99), but in 1805 became Professor of Botany at Madrid, and by Joseph Bonaparte was

appointed Minister of the Interior and Governor of Malaga (1808–13). Retiring to S. America (1814), he joined Bolivar, and after rising to be Intendant-General of the forces, held the Vice-Presidency of Venezuela (1818–19). Ill-health, however, compelled him to revisit Europe, and having as minister-plenipotentiary concluded a Colombian loan of £2,000,000 with London bankers, he died at Bath, 22d November 1822.

Zebid', a town of Yemen (q. v.), Arabia, on the Zebid, 60 miles N. of Mocha. It is an old town, with a large mosque, and a considerable but declining trade. Pop. 8000. From 819–1022 it was the residence of a sheik, and for a hundred years the seat of a great Arab school.

Ze'bra (*Asinus* or *Equus Zebra*), a species of *Equidæ* or *Solidungula*, distinguished from the ass and horse by the black striped bands which ornament both body and legs. The colour is a whitish yellow. The stripes run at right angles to the axis of the region in which they occur. Thus, those of the body are vertical, while those of the legs are horizontal. The tail is somewhat tufted and there is a short bristly mane. The Z. is fierce, active, and untamable. It is wary and fleet, and succeeds in making its way in districts which would be well-nigh impassable to the horse and its neighbours. The Dauw or Burchell's Z., also named the Peechi, differs from the Z. in having no stripes on the lower limbs, while those of the body are not so black as in the true Z. The Quagga (*Asinus quagga*) wants the stripes seen on the legs in the Z. The ass and Z. will breed together, and when a mare has borne a colt to a Z. stallion, the subsequent progeny of the mare by ordinary horses are striped like the Z.

Zebu' (*Bos Indicus*), a species of ox representing the domestic cattle of India, and distinguished by a curious fatty hump borne on the withers of the animals. The dewlap is also well-developed, and hangs in a heavy fold from the throat. The back droops markedly towards the tail. The Z. race numbers several well-marked breeds. Some are not much larger than big dogs; others exceed the ordinary ox. The sacred Brahmin Bulls belong to the Z. race. The horns are short. The Z. is used as a beast of draught, and also for riding. It is said to carry its young for 300 days, the period of gestation in the common ox being 270. The Z. is found in India, China, E. Africa, and Madagascar.

Zebu', or **Oebu'**, one of the Bissaya group of the Philippine Islands (q. v.) E. of Negros. Area 2352 sq. miles; pop. (1874) 427,356. The capital, Z., is a well-built town with a fine cathedral and episcopal palace. It was declared an open port in 1842, and has been the seat of a British vice-consulate since 1865. The harbour can be entered in both monsoons, but the northern entrance is narrow. In 1877, 22 vessels of 14,982 tons were loaded here, of which 9 of 6688 tons were British. The exports were—sugar, 12,145 tons; tobacco, 1,666,600 lbs.; hemp, 25,582 bales; sapan wood, 72 tons. Their total value was £300,000. Pop. 8800.

Zeb'ulun (Heb. 'dwelling') was the tenth son of Jacob (Gen. xxx. 20), and the tribe numbered 57,400 at the first census, and 60,500 at the second (Numb. i., xxvi.). The territory of Z. was one of the richest and most beautiful sections of the land of Canaan, stretching across the country almost from the Sea of Galilee on the E. to the plain of Phœnicia on the W. In after times the tribe was distinguished for its warlike spirit (*cf.* Jud. iv. 6, 10; v. 18), scientific skill (Jud. v. 14; 1 Chron. xii. 33), and commercial enterprise (Gen. xlix. 13; Deut. xxxiii. 18, 19).

Zechari'ah, the author of the book in the Bible bearing that name, was a prophet in the time of Darius Hystaspes (i. 1, 7; vii. 1), being thus a contemporary of Zerubbabel, Joshua, and Haggai (*cf.* Ezra v. 1, 2; vi. 14). Chaps. i.–viii. contain a series of visions relating to the rebuilding of the Temple and the exaltation of Jerusalem. It has been debated in modern times, however, whether the latter part of the book (chaps. ix.–xiv.), which does not seem to have any visible connection with what goes before, was composed by this prophet, or by one or more prophets of an earlier time. Thus chaps. ix.–xi. have been ascribed to Jeremiah on the ground that Matt. xxvii. 9, 10, which does not occur in Jeremiah, is probably quoted from Z. xi. 12, 13. There seem to be grounds for believing, at anyrate, that the prophecies of this second part were composed before the time of Z., or before the Captivity, and were afterwards united with those of Z., the compiler believing that they proceeded from the same writer. This in turn has been explained by supposing that the earlier section was written by some one of the same name, which was a common one. There was one in the reign of Ahaz, *e.g.*, mentioned by Isaiah (viii. 2), whose father even bore the same name as the father of Z. (i. 1, 7). See Wright's *Z.*, &c. (*Bampton Lectures*, 1878).

Zech'stein, a technical term applied by German miners to a stratum of Dolomitic limestone immediately overlying the Kupferschiefer or Mergel-schiefer. The latter is a marl-slate, containing copper-pyrites, besides numerous fossils, and much worked in Germany as a valuable ore of copper. Both formations correspond to the Middle Permian of English geologists.

Zedeki'ah, the last king of Judah, was the son of Josiah (q. v.). Originally called Mattaniah, he received the name of Z. from Nebuchadnezzar, when the latter placed him on the throne in the room of his nephew Jehoiachim, who was sent off to Babylon. Thus placed at the helm of the state at a great crisis in its history, Z. showed himself wanting both in the wisdom and firmness necessary to guide it aright. Thinking to throw off the yoke of the Chaldæans by help of the Egyptians, he only brought on his country the power of the former to crush it. After a siege of a year and a half by the Chaldæan army Jerusalem was taken (B.C. 588), and Z., who had attempted to escape, was captured, blinded, and sent in chains to Babylon, where he died.

Zee'land, the most S.W. province of the Netherlands, bounded N. by South Holland, E. by North Brabant, S. by Belgium, and W. by the North Sea. Area, 681 sq. miles; pop. (1877) 187,046. Z. is made up of the islands lying between the mouths of the Scheldt, South, North, and East Beveland, Walcheren, Wolfaartsdyk, Schouwen, Duiveland, Tholen (with St. Philippsland), and the so-called 'States Flanders.' The soil of Z. is exceedingly fertile and well tilled, yielding rich crops of wheat, flax, and hemp. Horses, horned cattle, sheep, and swine are reared, and on the coasts many live by oyster and other fishing. The chief manufactures are madder and calico. Shipbuilding, brewing, distilling, and salt-refining are also carried on; and in 1875 the Z. fisheries employed 472 boats and 1026 men. The transatlantic trade of Z. has declined since the 18th c. in consequence of the sanding up of the harbours. It is hoped that trade will be improved by the new harbour at Flushing and the recent connection of Z. with the German railway-system by Breda and Boxtel. The chief towns are Middelburg (q. v.), Flushing (q. v.), Zieriksee (pop. 7617), and Goes (pop. 6063). Z. has been won from the sea since the beginning of the Middle Ages, and has been broken up into islands by subsequent inundations. It originally belonged to the German Emperor, of whom at one time the Counts of Flanders, at another those of Holland, held it as a fief. These counts became independent in the 10th and 11th centuries, and long struggled for its possession, till Florens V. of Holland obtained it in 1269 as a dowry with Beatrix, daughter of Guido of Flanders. United to Holland ever since, it was one of the United Provinces, and joined in 1579 the Union of Utrecht.

Zeithun', a district of Cilicia, Asiatic Turkey, inhabited by a body of Armenian Christians. It is fertile but mountainous, and the people, who are almost independent of Turkish authority, are distinguished by their martial spirit and their immunity from crimes of violence. There is also a town of Z., with a pop. of about 20,000. This singular community is a survival of the Armenian kingdom which subsisted in Cilicia from the 11th to the 14th c. A sanguinary conflict which took place here soon after the Crimean War first drew the attention of Europe to this people. It was put a stop to by the intervention of the British and French consuls. In the spring of 1879 the Turkish pasha, enraged at the depredations of some neighbouring marauders, sent troops against the city, and the intervention of the English consul at Beirut alone saved it from destruction.

Zeitz, a town of Prussia, province of Sachsen, on the White Elster, 261 miles S. by W. of Leipzig by rail. It has five squares, an evangelical cathedral, three evangelical churches, an ancient Rathhaus, a good library with valuable MSS. and 20,000 vols.,

an hospital, &c. Z. manufactures woollen and cotton goods, sugar, leather, gloves, earthenware, pianos, waxcloth, &c.; there are also corn-mills and distilleries. Pop. (1875) 16,480. For its interesting history see Roth, *Aus der Geschichte der Stadt Z.* (Zeitz 1876).

Zela'ya, a town of Guanajuato, Mexico, on the Rio Grande de Santiago, 120 miles W.N.W. of Mexico. It has a large and elegant cathedral, with several other churches. The suburbs are squalid, and are inhabited chiefly by Indians. Z. manufactures cotton. Pop. 11,000.

Zelko'na Tree, a name given to *Planera Richardi*, a large elm-like tree, native of the Orient. The timber is much prized, the heartwood when dry being exceedingly hard, capable of a fine polish, and is an excellent furniture wood.

Zell, Karl, a well-known humanist, born at Mannheim, April 8, 1793, studied philology at Heidelberg, Göttingen, and Breslau, and became professor in the Rastatt Lyceum in 1814, and in the University of Freiburg in 1821. Here he founded a school of philology in 1830, and in 1835 was nominated to the ministerial council. In 1847 he became Professor of Archæology at Heidelberg, and from 1848 to 1853 he sat in the Second Chamber of Baden. At the diet of 1851 with Hirscher he exerted himself to promote the greater freedom of the Church. In 1855 he retired from his chair, and died at Heidelberg, January 24, 1874. Z. edited a collection of Latin classics (17 vols. Stuttg. 1827-31), to which he himself contributed the Phædrus, the Horace, and the *De Republica* of Cicero. He next edited the *Ethica Nicomachea* of Aristotle (2 vols. Freib. 1833), and translated the *Organon* (5 vols. Stuttg. 1836-40). His chief works, however, are *Ferienschriften* (3 vols. Freib. 1826-23; new issue Heidelb. 1857), *Handbuch der Römischen Epigraphik* (3 vols. 1850-57), and *Li-oba und die frommen Angelsächsischen Frauen* (Freib. 1860). He also published *Ueber die Iliade und das Nibelungenlied* (Karlsr. 1843), and his course of university lectures as *Opuscula Academica* (Freib. 1857).

Zell'er, Eduard, a German Protestant theologian and philosopher, born 22d January 1814 at Kleinbottwar in Würtemberg, studied theology first at Tübingen under Baur, then at Berlin (1836-37), and settled as *privat-docent* at Tübingen in 1840. In 1842 he started the *Theologische Jahrbücher*, an influential organ of the Tübingen school. Z.'s extreme critical views excluding him from a Tübingen theological chair, he accepted in 1847 a call to be extraordinary professor of theology at Bern. Here his appointment excited great opposition on the part of the Conservatives, yet Z. maintained his position till 1849, when he became professor at Marburg. Transferred to the faculty of philosophy at the instance of his opponents, he laboured with growing success as professor of philosophy at Heidelberg from 1862 till appointed successor to Trendelenburg at Berlin (1872), a position which he still (1879) holds. His chief works are *Platonische Studien* (Tüb. 1839), *Die Philosophie der Griechen* (3 vols. Tüb. 1844-52; 4th ed. 1876 *et seq.*; Eng. trans. 3 vols. 1868-75), *Geschichte der Christlichen Kirche* (Stuttg. 1853), *Das Theologische System Zwingli's* (Tüb. 1853), *Die Apostelgeschichte kritisch untersucht* (Stutt. 1854; Eng. trans. 1875), *Vorträge und Abhandlungen Geschichtlichen Inhalts* (Leip. 1865, 2d ed. 1875; 2d series, 1877), *Staat und Kirche, Vorlesungen an der Universität Berlin* (Leip. 1872), *Geschichte der Deutschen Philosophie seit Leibniz* (Leip. 1873), *David Friedrich Strauss in seinem Leben und seinen Schriften geschildert* (Bonn 1874), a work preliminary to his edition of *D. F. Strauss' Gesammelte Schriften* (12 vols., Bonn 1876-78), *Ueber die Lehre des Aristoteles von der Ewigkeit der Welt* (Berl. 1878), and *Ueber die Griechischen Vorgänger Darwins* (Berl. 1878).

Zemindar' (*Zamîndâr*, from an Arabic word meaning land), the name universally given in India to the landlords, who have engaged to pay the government land-revenue, as opposed to the *Ryots* (q. v.), who are the actual cultivators of the soil. The *zemindary* system, as it is called, by which the State accepts from the Z. a permanently fixed sum as its quota of the produce of the soil, and disregards all other interests, is found in its fullest development in Bengal, where it was established by the Permanent Settlement of Lord Cornwallis in 1793; but it exists to a minor degree in Madras and other provinces. There is little doubt that under the Mogul administration the Z. was merely a government official, charged with the collection of the revenue, with no rights in the land. But this office, like all others under a weak Oriental government, tended to become hereditary; and it is not surprising that the English, partly from short-sighted motives of convenience, should have been anxious to import their own system of landlord and tenant into a country where the absolute proprietary right of the State in the soil had never before been questioned. In Bengal, at the present day, the Z. has all the rights of a British landed proprietor, subject of course to the payment of the land-tax, and also to a certain ill-defined 'tenant right' on the part of those cultivators who have been for a long time in possession of their farms. Comparatively few of the Zemindars are now the descendants of those with whom the Permanent Settlement was originally concluded, and the subdivision of property is proceeding rapidly, as also is the creation of subtenures. The land revenue of Bengal was fixed in 1793 at £2,858,772. The rack-rent now received by the Zemindars is perhaps tenfold that amount. About one-fifth of the area of Madras is held under a Z. tenure, yielding a fixed revenue of £513,299. The so-called Zemindars in other provinces are usually liable to a periodical enhancement of the land demand.

Zena'na, or **Zana'na** (Pers. 'belonging to women'), that part of a house which among Hindus of good caste is set apart for the use of women. In Bengal a native gentleman's house consists of an outer and an inner part. Each of these is in the form of a quadrangle. The former, well furnished, with fine rooms, and windows looking out upon the public street, is for the use of the men; the latter, of a mean and even squalid appearance, is devoted to the women, who may go into each other's rooms, or take an airing in the courtyard, but must not be seen in public. From 50 to 100 Hindu ladies are sometimes gathered together in this dismal prison-house. Till about twenty years ago no Christian woman was permitted to enter a Bengal Z. The Rev. J. Fordyce was the first to organise the Z. Mission there, and Mrs. Mullens, an accomplished authoress in the Bengalee language, developed the system. In all the great centres of city and intellectual life in India, thousands of Hindu, and in some cases Mohammedan, ladies are now systematically taught in their own homes by Christian ladies, native, European, and American. A Government inspectress in many cases reports on the secular instruction imparted, and grants-in-aid are given accordingly. The sole difficulty is to train a sufficient number of vernacular Christian female teachers to meet the demand. Thus ever-increasing efforts are being made to reach the Hindus of the next generation by bringing the light of the gospel to brighten the cheerless hearths of Hindu mothers.

Zend, the name given to the primitive language of the Persian race, in which the sacred books or Z.-Avesta (q. v.) are written. The word itself is of uncertain origin. According to Max Müller, it is identical with the Sansk. *khandas* (Lat. *scandere*), 'metre;' but the accepted derivation is from the Sansk. *gnati*, 'knowledge,' being thus the commentary of which the Avesta is the original text. From the point of view of comparative philology, Z. possesses an importance and interest second only to Sanskrit. Its discovery, or rather its successful decipherment, dates from the present century. Preserved only in the Z.-Avesta, it remained unknown, or at least unintelligible, to European scholarship, until the enthusiasm of a French traveller, Anquetil Duperron, brought back an imperfect translation of the Z.-Avesta from India in 1761. A learned Dane, Rask, followed in his steps, and published the first scientific treatise on the language in 1821. It was the great French philologer, Eugene Burnouf, who definitely assigned to Z. its true place among the offshoots of the august Aryan stock. Though existing in comparatively few fragments, much corrupted by dialectal decay, Z. is now admitted to take rank as an elder sister, more primitive than either Greek or Latin, and almost contemporaneous with Sanskrit. As a spoken language, it is thought to have become extinct in the 3d c. B.C. In richness of grammatical modifications, and in redundancy of forms for composition, as well as in general similarity of radical framework, it closely approaches the classical Sanskrit of the Vedas. In fact, the farther we trace back Sanskrit to its earliest forms, the greater is the resemblance between the two. The evidence of a common mythology and ceremonial also points to the conclusion that the Sanskrit-speaking Hindus and the Z.-speaking Iranians lived together under the generic name of Aryas in the N.W. of Hin-

dustan, long after the ancestors of the Greeks, Romans, Celts, and Germans had separated from the original hive on their march towards Europe. It has been plausibly conjectured that a religious schism, embodied in the creed of Zoroaster (q. v.), was the proximate cause of the subsequent divergence of the Iranian or Persian race. The near connection of the two languages may be inferred from the following facts: Many Z. words can be transliterated into Sanskrit, merely by changing the letters into their corresponding forms, the main difference being in the sibilants, nasals, and aspirates; *e.g.*, the *Sapta Sindhu* or Seven Rivers of the Vedas, becomes *hapta hendu* in the Z. Avesta. The forms of the two words 'India' and 'Hindu' show that we have derived them from 'Sindhu' through a Greek and Persian channel respectively. Up to 100 all the Aryan languages count in substantially the same numerals; but *sahasra*, Sanskrit for 1000, is only represented in the Z. *hazara*. If modern Persian stands to Z. in the same relationship that Italian does to Latin, then Z. and Sanskrit may be compared to two dialects of Classical Greek. The chief authorities on the philology of Z. are Burnouf, Bopp, Spiegel, Westergaard, West, and, above all, the late Dr. Martin Haug, for many years professor in the Poonah College, Bombay. For a popular explanation, see Max Müller's *Chips from a German Workshop*, vol. i.

Zend-Aves'ta, more properly **Aves'ta-Zend'** (usually interpreted to mean 'authorised text' and 'commentary'), the religious book of the Parsees (q. v.), or representatives of the old creed of fire-worshippers. The original is written in the primitive Zend (q. v.) language, with a translation into the comparatively modern Pehlvi (q. v.) made by order of the Sassanian dynasty, 235–651 A.D. In antiquity, the Z.-A. ranks second to the Vedas, while its language is also the nearest sister of the Sanskrit. Traditionally, the whole is regarded as the composition of Zoroaster (q. v.), to whom it was directly revealed. But modern scholarship is able to discriminate between different portions, and assign each approximately to its own period. The oldest part may possibly date back to 1200 B.C. What is now in existence is evidently but a very small portion of the complete work, which is reported to have consisted of 21 *nosks* or volumes, of which only one, the Vendidad, now survives in its entirety. In addition, the sacred text contains the Yazna, the Visparad, and the Yasht. These are mainly composed of hymns and sacrificial prayers, addressed either to Ormuzd or to the numerous archangels and powers of nature. The Yazna includes five Gathas or prayers—the only portion of the Z.-A. which modern criticism is disposed to assign to Zoroaster himself. The Vendidad, which has been called the Pentateuch of the Parsees, is a code of ceremonial observance, prescribing rules of purity for daily worship and the ordinary business of life. The general conception of the whole may be briefly described as Monotheism of a lofty type, tinged with traces of an earlier mythology, and gradually crystallised in the forms of sacrificial worship. At the present day, every Parsee child is taught to repeat long passages in the original Zend; but hardly a single word of that language is intelligible even to the Parsee priests or Dasturs. It has been the boast of Western scholarship to restore to the Parsees the right understanding of their own sacred book. The first translation into French by Anquetil Duperron, published at Paris in 1771, was received with scepticism by the greater part of Europe. It required the accurate philology of Burnouf to attract serious attention to the subject. His edition, the first of the original text, was published at Paris 1829–43. But the interpretation of the Z.-A. is still a matter of great doubt and difficulty. As compared with the Vedas, the total amount of Zend literature in existence is extremely scanty. What we do possess was handed down for centuries by oral tradition, then translated into a modern dialect of the same language, and finally preserved by the fidelity of a wandering priesthood, who now use Gujerathi, a Hindu dialect, as their vernacular. Under these circumstances, it is not surprising that rival scholars should often differ widely about the decipherment of certain passages. Sufficient has been definitely ascertained to render the study one of extreme interest and steady progress. See Dr. Martin Haug's *Essays* (1st ed. Bombay 1862); and Abel Hovelacque's *Grammaire de la Langue Zende* (Par. 1878); also Spiegel, *Avesta: die heiligen Schriften der Parsen, aus dem Grundtext übersetzt* (3 vols. Leip. 1852–63); Harlez, *Avesta, Livre Sacré des Sectateurs de Zoroastre* (Liege, 3 vols. 1875–78).

Zenick (*Suricata Zenick*), a species of Carnivorous quadruped, allied to the Ichneumon, and also named the 'Suricate.' It is found in S. Africa, attains a length of 18 inches, and resembles a weasel, but has longer legs. The colour is a greyish brown, marked on the back with cross bands of darker hue. The muzzle is sharp and the tail long, but sparsely covered with hairs. The Z. may be domesticated, and is a dreaded enemy of rats and mice. It also feeds on fruits.

Zen'ith, the point in the heavens directly above an observer, being thus the upper pole of the observer's horizon, and diametrically opposite the Nadir (q. v.).

Zenjan', or **Zengan'**, a town of Persia, province of Ajemi, on a tributary of the Kizil Uzen, 200 miles W.N.W. of Teheran. Girdled with old walls and orchards, it is an important place on the line between Teheran and Tabriz, and carries on a large trade in carpets, arms, and salt. Pop. 20,000.

Ze'no, the name of two Greek philosophers. (1) Z., the Eleatic, born about 500 B.C., was a follower of Parmenides. He attempted to support the position that only 'the one' or pure Being must exist, by a negative criticism against the possibility of multiplicity and motion. His arguments were advanced with great acuteness, and first directed attention to certain difficulties and antinomies involved in the infinite divisibility of matter, space, and time. (2) Z. (350–258), the founder of the Stoics (q. v.), was a merchant of Cittium, in Cyprus, who lost his all by a shipwreck, and thus forced to serious reflection, determined to apply himself to philosophy. He studied for twenty years under various masters, and then opened his school. He is said to have ended his life by Euthanasia. The Athenians, in admiration of his noble character, built his tomb at the public expense, and erected a monument on which the inscription was carved, 'His life corresponded to his precepts.' No philosophical doctrines in ancient times produced such noble fruits as those of the Stoics. The truest men in the Roman world were followers of Z. The latest writers of note on Z. of Cittium are Weygoldt (Jena 1872), Wellmann (Leip. 1873), and Wachsmuth (Gött. 1874).

Ze'no, Roman Emperor of the East (474–491), born of a noble family, married Ariadne, daughter of Leo I. (468), was preceded on the throne by his own son, Leo II., whom his father-in-law before his death recognised as his successor. For some time Z. was joint-ruler with, though subordinate to, his son; but on the death of the latter in 474 he became sole emperor. His reign was very unfortunate. The barbarians ravaged the empire on all sides, and his own subjects rose in revolt against his cruel and oppressive government. These rebellions were crushed by murder and bribery, but as often as they were crushed they broke out again, whilst the barbarians, who were continually attacking the empire, were bought off by disgraceful concessions. Z. died in 491, after a reign of seventeen years, and was succeeded by Anastasius, who married his widow. See Tillemont's *Histoire des Empereurs* (vol. vi.), Gibbon's *Decline and Fall* (chap. xlvii.).

Zeno'bia, queen of Palmyra (q. v.), succeeded to the throne as regent for her sons on the murder of her husband Odenathus, 266 A.D. Not content, however, with the independence granted by the indolent Emperor Gallienus and his successor, Claudius, she aimed at a dominion which should include Egypt, Syria, and Asia Minor, and make good her vaunted title of Queen of the East. The accession of Aurelian, however, in 270, once more placed a soldier at the head of the Roman empire, and in 273 the armies of Z. were defeated in two pitched battles, while Palmyra was taken and its queen made prisoner. According to Zosimus she died on her way to Rome, but according to Trebellius Pollio, whose narrative is much more particular, she was led in triumph through Rome in the train of Aurelian, and was afterwards presented by her conqueror with a villa at Tibur, where she passed the remainder of her life with her sons after the manner of a Roman matron. Z. was one of the most remarkable women of antiquity. She resembled Cleopatra in her talents and her personal fascination, but she far surpassed her in purity and elevation of character. 'She is,' says Gibbon, 'perhaps the only female whose superior genius has broken through the servile indolence imposed on her sex by the climate and manners of Asia.' See Von Sallet, *Die Fürsten von Palmyra unter Gallienus, Claudius und Aurelian* (Berl. 1867).

Zen'ta, or **Czen'ta**, a town of Bacs, Hungary, on the Theiss, 24 miles S. of Szegedin. It lies in a fertile country, producing abundant crops. Cattle are largely bred. Pop. (1869) 16,808. Prince Eugene defeated the Turks here in 1696.

Ze'olite (Gr. *zeô*, 'I boil'), a generic term applied to a very large family of secondary minerals, supposed to have been formed by the action of water upon the original constituents of volcanic rocks. They are all hydrated silicates, mostly of the alkalies and alkaline earths, and containing from 10 to 25 per cent. of water. They occur usually in cracks and crevices in traps and other ancient igneous rocks, and as typical examples may be mentioned Analcime, Apophyllite, Stilbite, and Natrolite. The name Z. is derived from the circumstance that all these minerals froth and bubble up when heated in the flames of the blow-pipe.

Zephani'ah (Heb. 'watcher of the Lord'?), a Hebrew prophet, flourished in the reign of Josiah, 7th c. B.C. He is the ninth in order of the twelve 'minor prophets.' His little book (of three chapters) predicts the desolation of Judæa as a punishment for the idolatry and worldliness of its inhabitants, calls upon it to repent, announces the destruction of its surrounding enemies, and ends with a declaration that God will make the righteous remnant of Israel 'a name and a praise among people of the earth.'

Zerbst (Wend. 'belonging to the Sserbski'), a town of Germany, Duchy of Anhalt, formerly capital of the principality of Anhalt-Z., on the Nuthe, 26½ miles S.E. of Magdeburg by rail. The chief buildings are the Nikolaikirche, dating from the 15th c.; the great Schloss, surrounded with a park; and the stately old Rathhaus, dating from the 15th c., but disfigured by additions in 1610, standing in the market-place, in the centre of which are the Roland Column (1445), and the Butterjungfer, a slender column bearing a female figure. Z. contains a gymnasium of high repute —the Franciseeum—and has manufactures of silks, plush, cloth, leather, gloves, gold and silver lace, soap, starch, essences, tobacco, chemicals, pottery, umbrellas, musical instruments, and machinery. Gardening, iron-founding, and beer-brewing are also carried on. Pop. (1875) 12,877.

Ze'ro, in physics, is any convenient point with reference to which quantitatively estimable phenomena of the same kind are compared. Thus, on the centigrade scale, the Z. of temperature is chosen as the temperature of freezing water; while the absolute Z. of temperature is a point determined by thermodynamic principles (see HEAT). In Electricity (q. v.) any object is at Z. potential when it is in contact with and is at the same potential as the earth. A Z. has the essential characteristics of what is known in analytical geometry as the origin.

Zeulenro'da, a town of Germany, in a detached portion of the principality of Reuss-Greiz, 10 miles W. of Greiz, has a large handsome *stadtkirche*, a beautiful *rathhaus* and hospital, with important manufactures of soap, machinery, cotton and woollen wares, especially hosiery, besides a considerable trade in cattle. Pop. (1875) 6900.

Zeus ('the god of the bright heaven') is the supreme deity of the Hellenic religion, the ruler of gods and men, 'whose eye sees all and knows all' (Hesiod), who, himself goodness and love, 'grants whatever he will in his mind, for he can do all things' (Homer). The original meaning of his name is clearly seen in such words like *Diosēmeia* ('portents in the sky'), *Diipetēs* (lit., 'fallen from heaven'), *endios* ('in the open air'), *eudios* ('well-skyed'), and the Latin *Sub Jove frigido, sub diu, sub dio, sub divo.* It is the same as the Sansk. *Dyu, Dyaus;* Lat. *Jovis*-pater, *Ju-* in *Jupiter*; O.H.G. *Ziu;* Old Eng. *Tuo* or *Tiu*, preserved in *Tiwesdæg*, 'Tuesday' (q. v.), the day of the Eddic god *Ty*. 'For good and for evil, Z. the Sky and Z. the God were wedded together in the Greek mind' (Max Müller). Throned in the upper æther Z. was worshipped by Hellenes of every clan. The tops of the highest hills of Hellas were sacred to him, and specially was Mount Lykaion, which overlooks all Arcadia, consecrated to his worship. In the earliest phase of the Hellenic religion, the cloud-compelling Z. blesses the thirsty fields with rain and dew (*cf.* the Roman *Jupiter Pluvius, Serenator*, and *Lucretius*), cherishes the woods, the hearths, and the flocks (*Z. Herkeios*). The oak-tree and the thunderbolt are his earliest symbols. In the Theogony of Hesiod Z. is the culminating point of the unfolding Kosmos, which, from abstract physical beginnings (*Okeanos, Chthōn, Chaos*), grows ever more concrete. He quells all hostile powers, and gives the world of gods and men its normal form. In Homer, Olympos, the snowy mount of Thessaly, is the throne of Z. 'the father, the most glorious, the greatest, ruling over all, mortals and immortals.' Æschylus and Pindar are the greatest exponents of Hellenic faith in supreme Z. With them he is the all-blessed lord of lords, the 'lord of infinite time,' the eternal father, who gives to all according to their deserts, who is full of mercy to the pious suppliant, of holy wrath against transgressors. 'Z.,' says Æschylus, 'is the earth, the air, the sky; Z. is all and above all.' 'He leads men in the way of wisdom; he orders that suffering should be our best school.' In relation to civil society, Z. is the embodiment of law and order, the guardian of friendly intercourse, of the state (*Z. Polieus*), of the rights of citizens (*Z. Horios*) and strangers (*Z. Xenios* and *Hikesios*), and in war he is the leader and the victor, the liberator and the saviour. In a wider political relation, Z. is the head of all unions and alliances. He is the chief patron of gymnastic contests, and of soothsaying, 'for he sees all things, and holds the future in his hands.' The oak-tree at Dodona and the Ammonium were his oracles, and at Delphoi he spoke by the mouth of the Pythian Apollōn. The mythic history of Z. grew out of many local traditions. Hesiod tells that he was born in Crete, whither Rhea had been conveyed by Gaia for fear of his father Kronos. Later writers state that the precise spot was a cave of Mount Ida there, and that he was nursed by Amaltheia (q. v.). When he grew up he freed the Cyclōpes (q. v.) and the Giants, and having overpowered the Titans (q. v.), gained the dominion of the world, which neither the Giants and Typhōn (q. v.) nor the Titanic intelligence of Promētheus (q. v.) could wrest from his grasp. Hēra is in Homer and the older poems generally the sole wife of Z., the oldest and greatest of the goddesses, but in Hesiod his first union is with *Mētis* ('wisdom'), after whom come Themis, Eurynomē, Dēmētēr, Mnēmosynē, and Hēra. The brother of Hestia, Dēmētēr, Hēra, Poseidōn, and Hadēs, Z. is the father of all the other gods and heroes that dwell in heaven, Athēna, Hēphaistos, Apollōn, Arēs, Aphroditē, Hermēs, the Dioskouroi, Perseus, and Hēraklēs. Themis, the Hōrai, the Muses, the Charites, and the Moirai are his attendant deities. The myths of the loves of the Sun, which the poets delighted to sing, are either based on country tales of the adventures of the Sun as the great fructifying principle, as in the case of Lētō, Io, Dēmētēr, Maia, Danaē, Kallistō, or owe their origin to the pride of families like the Aiakidai or the Hērakleidai. In artistic representations Z. appears either as a youth, or as a man in his prime, or as an old man. His statues express kingly majesty, and are usually either sitting or standing. In his most famous statue at Olympia by Phidias, Z. sat on a throne of gold and ivory 43 feet high, on a base 13 feet high. The chief representations of Z. now extant are the Otricoli mask, now in the Vatican; the bronze of Paramythia, in the British Museum; two statues at Florence, a bust at Vienna, and a number of wall-paintings found at Pompeii and Herculaneum, and now in the Museum at Naples. See Grote's *Greece* (vol. i.); Max Müller's *Lectures* (2d series); and Cox's *Comparative Philology*; Welcker, *Griechische Gottenlehre* (3 vols. 1857-63); Overbeck, *Griechische Kunstmythologie* (Leip. 1871); Hartung, *Die Religion und Mythologie der Griechen*, vols. i.-iv. (1873); Preller, *Mythologie*, vol. i. (3d ed. 1873); Von Sybel, *Das Bild des Z.* (Marburg 1876).

Zeuss, Johann Kaspar, the founder of Celtic philology, was born at Vogtendorf in Oberfranken, Bavaria, July 22d, 1806. From the Lyceum at Bamberg he passed to the University of Munich, where he devoted himself to philology and history. In 1839 he became professor of history in the Lyceum at Speier, and in 1847 in that at Bamberg. He died at Vorstendorf, near Kronach, November 10th, 1856. His historical works are, *Die Deutschen und die Nachbarstämme* (Münch. 1837), *Die Herkunft der Bayern von den Markomannen* (1839), *Traditiones Possessionesque Wizenburgenses* (Speier 1842), and *Die freie Reichsstadt Speier vor ihrer Zerstörung* (1843). His great work is his *Grammatica Celtica* (2 vols. Leip. 1853; 2d ed., by Ebel, Berl. 1868-71), which for the first time placed Celtic philology on a scientific basis.

Zeux'is, a famous Greek painter, probably born at Heraclea on the Euxine about 450 B.C., was of the Ionic school, and unrivalled in rendering types of sensuous beauty, though Aristotle says he failed in his attempts at high moral characterisation. His 'Helen,' executed for the Croton temple of Juno, and combining the perfections of five Croton virgins, was looked upon as the ideal type of beauty. Among his other masterpieces are his 'Hercules Strangling the Serpent,' 'Jupiter among the Gods,' 'Marsyas Bound,' and the 'Female Hippocentaur.' The well-known story of his contest with Parrhasius is of a piece with the tradition that he died of laughter at his own picture of an old woman.

Zeyst, or **Zeist**, a village in Utrecht, Holland, not far from the Utrecht-Arnheim railway, has a Dutch Reformed, Roman Catholic, Separatist, and Herrnhuter church. It manufactures porcelain, wax-candles, soap, and turned wares. Pop. (1876) 5626. In the neighbourhood of Z. an obelisk commemorates the Union of the Seven Provinces of the Netherlands, effected here in 1579.

Zib'eth (*Viverra Zibethia*), a species of *Viverridæ* or Civets (q. v.) found in E. Asia, and attaining a length of from 3 to 4 feet. The colour is a brown mixed with white, and marked with spots and blotches of darker hue. The Z. has a musk-secreting pouch resembling that of its African neighbour the true civet (*Viverra civetta*).

Zier'ikzee, a town of the Netherlands, province of Zeeland, and the chief town of the island of Schouwen, 3 miles from the Ooster Schelde (with which it is connected by two canal-harbours), and 21 miles E.N.E. of Flushing. Z. has six churches, a fine town-house, and a gymnasium, manufactures madder, carries on brewing and oyster-fishing, and has considerable trade and shipping. It is the oldest town of Zeeland, and was formerly an important Hanse town. Its demolished walls are now replaced by promenades. Pop. (1876) 7617.

Zie'then, or **Zie'ten, Hans Joachim von**, one of the bravest and most popular generals of Friedrich the Great, was born at Wustrau, May 18, 1699, entered the Prussian service in 1714, retired in 1724, but re-entered it as a lieutenant in 1726. A quarrel with his captain next brought him a year's imprisonment and his dismissal from the service. Restored to his rank in 1730, he became captain in 1731, and major in 1736. In 1741 he became colonel of a regiment of hussars, and in this capacity did much to increase the efficiency of the Prussian light cavalry. At the outbreak of the Second Silesian War (1744), at the head of the advanced guard he entered Bohemia, advanced to Budweis, then achieved a dexterous retreat behind the Elbe, inflicting a signal defeat on a force of 16,000 men at Moldau-Tein, 12th October. In 1745, at Jägerndorf, he led his regiment, which wore a uniform similar to that of an Austrian regiment of hussars, through an Austrian force of 20,000, in order to carry to the Markgraf Karl the orders of the king, and took an active part in the battles of Hohenfriedberg (June 4th) and Hennersdorf (November 23), soon afterwards being made major-general. During the peace he fell under the displeasure of the king, but was forgiven at the outbreak of the Seven Years' War, and appointed a lieutenant-general. He took part in the battles at Reichenberg and Prague, commanded the left wing at Kollin, next remained near the Prince von Bevern, who wished to cover Lausitz and Schlesien, and on his defeat and capture, led the remnant of his army to join the king at Liegnitz. In the battle of Liegnitz (August 15, 1760) he held back the Austrian main army during the struggle before the camp, for which on the field of battle he was made general of cavalry. At Torgau he carried the Siptitz Heights, and thus decided the victory. In the spring of 1761 Z. watched the Russians, who, however, declined to give him battle. From this time until the close of the war he remained with the king, holding during his absence the supreme command. After the war he lived chiefly at Berlin, enjoying the especial favour of Friedrich, who was a frequent visitor of his 'old father Z.' He died at Berlin, January 26, 1786. A monument was erected to him at Berlin in 1794 by Friedrich Wilhelm II. His life has been written by Luise Joh. Leopold von Blumenthal (3d ed. Berl. 1806), and Hahn (5th ed. Berl. 1878).

Zill'eh, a town in the sandjak of Sivas, Asiatic Turkey, 34 miles S.S.W. of Tokat. It stands on a height, and a large mound rises in the centre of the town, crowned with a fort. Z. has some weaving; and at its great fair in November, lasting from a fortnight to three weeks, a large amount of business is done. Pop. 10,000. The ancient *Zela*, Z. has few traces of antiquity. Mithridates defeated the Romans, and Cæsar 'came, saw, and conquered' Pharnaces at Z.

Zill'erthal, one of the chief valleys of the Tyrol, is watered by the Ziller, an affluent of the Inn. It is about 50 miles in length, and is bounded in the S. and W. by great glaciers, but in the N., where it opens out into the valley of the Inn, it is tolerably fertile. Cattle-rearing is the chief occupation of the inhabitants, who number about 15,000. Many of these, however, wander over Europe for summer service. The chief town is Zell. See Streiter, *Bläter aus Tirol* (1868); and Löwe, *Aus dem Zillerthaler Hochgebirge* (Gera 1878). In 1830 a remarkable secession from the Roman Catholic Church began to take place here, and went on for some years. The difficulties of their new religious position compelled the seceders (400 in number) to emigrate in 1837. They found a refuge in Prussia, and settled at Erdmannsdorf, where they were assisted by a grant from the Prussian Government. In 1878 they numbered 225, but a large number had established themselves in other parts of Germany. See Beheim-Schwarzbach, *Die Zillerthaler in Schlesien* (Bres. 1875).

Zimb, the name given to a species of *Diptera* or Flies, allied to the *Tsetse* (q. v.), and believed to be the *Zebub* mentioned in Isaiah vii. 18. It occurs in Abyssinia, where it is exceedingly destructive to cattle. The elephant, rhinoceros, and camel also suffer from its attack. The average size is that of a bee. The Z. infests marshy soils.

Zimm'erman, Johann Georg von, a Swiss physician and philosopher, was born at Brugg, in the canton of Aargau, 8th December 1728, went in 1747 to the University of Göttingen, where he studied medicine under the immediate supervision of his distinguished countryman, Haller, and graduated with distinction in 1751, when he published a remarkable *Dissertatio Physiologica de Irritabilitate*. After travelling in France and the Low Countries he settled as a physician in Bern, marrying a young widow, a kinswoman of Haller. Shortly afterwards he received the appointment of town physician in his native place, Brugg, where he remained for sixteen years, gaining wide professional repute, and at the same time cultivating assiduously the literary and philosophical studies to which his tastes attracted him. He published a *Life* of Haller (Zür. 1755), and *Betrachtungen über die Einsamkeit* (Zür. 1756), a work which contained the germs of the later treatise with which his name is inseparably connected; *Vom Nationalstolze* (Zür. 1758), and his most noted medical work, *Von der Erfahrung in der Arzeneikunst* (Zür. 1763-67), which was translated into many foreign languages. Many offers were made to tempt him away from the comparative retirement in which he lived at Brugg, and in 1768 he accepted the post of court physician at Hanover with the title of Hofrath. Two years later he lost his wife, and in 1781 he was forced to go to Berlin to submit to a painful operation, which was successfully performed, but afforded only temporary relief from the illness which had made it necessary. Further family misfortunes—the death of his daughter and his son's loss of reason—now conspired to aggravate the constitutional melancholy to which he had always been a prey. He was in danger of sinking into a state of hopeless despondency, but was saved for the time by a second marriage, which had an excellent effect upon him. He now published his famous work *Ueber Die Einsamkeit* (4 vols. Leip. 1784-85), which redoubled his already considerable fame, and procured for him an invitation from the Empress Catharine to settle at the court of Russia, which, however, he did not accept. On his visit to Berlin in 1781 he had been warmly received by Friedrich II., who in his last illness in 1786 desired to have the advice of Z. He accordingly went a second time to Berlin, but found the king's case hopeless. The literary results of this visit were two works entitled *Ueber Friedrich den Grossen und meine Unterredung mit ihm kurz vor seinem Tode* (Leip. 1788), and *Fragmente ueber Friedrich den Grossen* (Leip. 1790). His alleged indiscretions in these works involved him in controversies which contributed to the embitterment of his latter years. His melancholia gradually increased, he became a prey to painful delusions, and died at Hanover, 17th October 1795. See *Z.'s Eigene Lebensbeschreibung* (Han. 1791); Marcard's *Beitrag zur Biographie des J. G.*

ven Z. (Hamb. 1796); Tissot's *Vie de Z.* (Lausanne 1797), and Bodemann's *J. G. Z.* (Han. 1878).

Zinc is a metal which has been known in a separate state only since the days of Paracelsus, although it has been used with copper in the alloy brass from very remote times. It did not come into any considerable prominence till about the middle of the 17th c., at which time the smelting of the ores was begun in various parts of Europe. At the present day the principal centres of Z.-smelting are Silesia, Belgium, England, and the United States of America. The most important ore of Z. is calamine, a carbonate of Z., $ZnCO_3$, a widely disseminated mineral obtained in Silesia, Belgium, the north of Spain, the Mendip Hills in Somersetshire, and many other localities. A silicate of Z., $ZnSiO_4H_2O$, known as siliceous calamine or Z. glance, is also an ore of some importance, very commonly associated with ordinary calamine. From the red oxide of Z. or spartalite, ZnO, which owes its colour to the presence of iron and manganese, a large amount of Z. is obtained in America. Z.-blende, the sulphide of Z., ZnS, is also an ore which is smelted largely. Z., or, as it is commercially called, spelter, is a bluish-white metal having an atomic weight of 65·0; its specific gravity ranges from 6·8 to 7·2; it melts at 773° F. and boils at 1904°, or, according to Becqueral, at 1636°. It volatilises at a red heat, and the vapour, if exposed to the air, burns with great brilliancy, emitting a luminous flame, at the same time forming zincic oxide which deposits in copious flocculent masses. Z. is a very brittle metal, but when heated to from 212° to 302° F. it becomes sufficiently malleable and ductile to allow of being rolled into thin sheets and otherwise worked. When exposed to moist air, Z. quickly becomes coated with a thin film of oxide which closely adheres to the surface and prevents the oxydising influence penetrating further into the metal. It is readily attacked by dilute mineral acids, a common means of preparing hydrogen being to place granulated Z. in a dilute solution of sulphuric acid.

In the extraction of Z. from its ores distinct processes are employed in different countries, the principal being the English, the Silesian, and the Belgian or Vieille Montagne process. In all cases the ore is first crushed between rollers, separated from impurities, and roasted on the sole of a reverberatory furnace. In this way zincic oxide is produced from any of the compounds, and the roasted mass is mixed with its own weight of anthracitic coal ground fine, after which it is ready for treatment by any of the plans above indicated. According to the English process the mixture is placed in closed crucibles within a low-arched furnace somewhat like a glass furnace in construction. In the bottom of each crucible is an opening to which is attached a short iron tube. A longer tube of larger bore fits to the end of the first tube, and beneath the open end of the second tube is an open iron vessel into which the Z. is received. The reduction is effected by a process of distillation, carbonic oxide coming off first, which burns with a blue flame at the end of the short iron tube. After a few hours the flame assumes a brown tint owing to the distillation of cadmium which is always mixed with the ores, and which being more volatile distils over before the Z. When the characteristic flame, a bluish white, of Z. appears, the long tube is attached and thereby the flame is extinguished. The metal then distils, partly as powder and partly in drops, and is received in the iron vessel into which the tube dips. It is thereafter re-melted, skimmed, and cast into ingots of spelter, or rolled into sheets. In the Silesian process the distillation is effected in closed retorts of peculiar form, having in one end apertures for charging and withdrawing the exhausted charge, and a bent tube for carrying off the distillate. These are arranged in two horizontal rows on the same plane, end to end, in a furnace or oven like a gas-retort bench, and they are now generally fired by the Siemens Gas Regenerative system. In the works of the great Vieille Montagne Company and others in Belgium, long cylindrical retorts are used which are placed in several tiers above each other in a high furnace. The retorts have an open end projecting out of the furnace, the inner end rests in niches in the back wall, and they have a gentle slope down to the mouth end, on which is luted a wide, conical cast-iron pipe which acts as a receiver for the distilled metal. At the open extremity of the receiver a sheet-iron tube is fitted by which the gaseous products are carried off. As many as forty or forty-five retorts are arranged in the same furnace, those in the higher tiers being charged with the poorer ores, for the reduction of which a less intense heat is needed than for the richer ones.

The uses of Z. are varied and important. It is very extensively consumed in the form of amalgamated plates in the construction of voltaic batteries. These plates are prepared by thoroughly cleaning the surface of Z. plates and dipping them into a strong solution of mercuric nitrate or chloride, or by simply rubbing over the plates, wet with dilute sulphuric acid, with metallic mercury. It is also largely used in preparing Galvanised Iron (q. v.), which consists of sheet or wire iron coated with Z., by dipping or passing the iron previously rendered chemically clean through a bath of molten Z., the surface of which is protected by a covering of sal ammoniac. In some cases a thin film of tin is first deposited on the iron surface by voltaic action before galvanising, and sometimes a little tin is added to the Z. bath. The metal also forms a series of valuable alloys, the most important of which are Brass (q. v.) and German silver. In 1877 the 57 mines of the United Kingdom yielded 24,405 tons of ore; in 1876 the yield of the German Empire was 533,559 tons of ore (449,374 from Silesia), and of the Austrian 13,226. The quantity of Z. smelted throughout the world during 1877 was estimated to amount to 178,690 metric tons, of which 49,377 were smelted in Silesia, 38,518 by the Vieille Montagne Company of Belgium alone, 6833 in the United Kingdom of Great Britain and Ireland, and 15,000 tons in the United States of America.

Medicinal Properties of Zinc.—Z. in its purely metallic state produces no medicinal effect upon the animal economy, but several of its compounds possess active medicinal properties. Granulated Z., which is used in the preparation of *liquor* Z. *chloridi*, Z. *chloridum*, and Z. *sulphas*, is prepared by fusing the Z. of commerce in an earthern crucible, heated to a sufficient degree to melt the Z., but not to produce combustion, which is then poured in a very thin stream into a bucket of cold water and afterwards dried. The following pharmaceutical preparations of Z. are contained in the British Pharmacopœia, viz., the *acetate*, the *carbonate*, the *chloride*, the *oxide*, the *sulphate*, and the *valerianate* of Z. *Acetate* of Z. is prepared by the action of acetic acid upon the commercial oxide of Z., and is obtained in thin, translucent, and colourless crystalline plates, of pearly lustre, which effloresce in a dry atmosphere, and are very soluble in water. The taste is astringent and metallic, and its properties are similar to those of the sulphate of Z., but it is probably somewhat less active. *Acetate* of Z. is used chiefly as an astringent collyrium in ophthalmia, in the proportion of one to two grains to a fluid ounce of water; or as an injection in gonorrhœa, after the acute stage has passed, in from 5 to 20 grains to the fluid ounce. *Carbonate* of Z. is made by precipitating the sulphate of Z. by the carbonate of soda, and is obtained as a white powder, closely resembling in its properties the oxide of Z. It is used in medicine as a cerate in the proportion of 1 to 5, and is prescribed, internally, in doses of from 2 to 10 grains. *Impure carbonate* of Z., or calamine, is used for making lotions, and for Turner's cerate. *Chloride* of Z. is prepared by the action of muriatic acid upon Z., and occurs in colourless, opaque rods or tablets, very deliquescent and caustic, and soluble in both water and alcohol. *Chloride* of Z. is sometimes prescribed internally in doses of from ½ to 1 or 2 grains, as an alterative and tonic, but it is chiefly used externally as a caustic and disinfectant. When applied in a concentrated form it causes intense pain, lasting from six to eight hours, and a whitish eschar is formed which usually separates in from six to twelve days, the slough being free from odour, but it is usually applied in the form of a paste. *Canquoin's Paste* is made by mixing the chloride of Z. with flour and water in the proportion of from one to three or one to six. When used, ten to fifteen drops of water are added to the paste, which is applied in layers, successive applications being required when a large tumour is to be destroyed. *Liquor Z. chloridi* is used as a disinfectant, and is commonly known as *Sir W. Burnett's Disinfecting Solution.* In cases of poisoning by chloride of Z., carbonate of soda should be freely given. When oxide of Z. is mixed with an equal weight of *chloride* of Z., the latter may be preserved dry enough to blow through a tube into any cavity required, as the cavity of a tooth after the removal of the diseased parts. *Chloride of Z. points* are also prepared by mixing one part each of *chloride* of Z. and *oxide* of Z. with two parts of wheat flour and a sufficiency of water to make a stiff paste, which is then moulded into points. *Oxide* of Z. is made by

heating the *carbonate* of Z. until the water and acid are driven off, when it appears as a soft, white, tasteless, and inodorous powder, insoluble in water, but soluble in dilute acids. *Oxide* of Z. is used internally in convulsive affections, especially in epilepsy and chorea, in doses of from 2 to 10 grains; but its chief use is as an astringent and absorbent in the form of powder or ointment to slight excoriations and ulcerations, and in cases of chronic eczema. When applied to the feet it destroys the unpleasant odour of perspiration. *Sulphate* of Z. occurs in minute, transparent, prismatic crystals which effloresce slightly in dry air and are soluble in water, but insoluble in alcohol. *Sulphate* of Z., in small doses, acts as a tonic and astringent; and, in a concentrated form, as an active irritant. In doses of 30 grains it acts as an efficient emetic; and in 2-grain doses it may be given as a stimulant astringent in chronic diarrhœa with ulceration. When taken in poisonous doses, alkalies and their carbonates should be given, and also eggs and milk. *Sulphate* of Z. is chiefly used, externally, as an astringent injection in fluor albus, the advanced stages of gonorrhœa, or as a wash for indolent ulcers, or a collyrium in ophthalmia. It is also used as a styptic. Sticks of fused *sulphate* of Z. are applied as an astringent to suppurating surfaces. *Valerianate* of Z. occurs in bright white tabular crystals with a feeble odour of valerianic acid and a metallic taste. It is prescribed in doses of from 1 to 6 grains as an antispasmodic in chorea, epilepsy, and in various neuralgic and hysterical affections.

Zincog'raphy is an art analogous to lithography, the stone printing-surface of the latter being replaced by a zinc plate. A novel method of printing facsimiles of rare prints, books, &c., from plates of polished zinc was invented in 1841 by Baldernus of Berlin, and introduced into England four years later by C. W. Siemens. It is called *Anastatic printing* (Gr. *anastasis*, 'a raising up'). A paper to be copied is wetted with dilute nitric acid, and brought into intimate contact with a plate of polished zinc. The portions of the zinc plate in contact with the unprinted parts of the paper are etched by the acid, and a reversed copy of the printing is thus 'set off,' and presents a slight relief on the plate. The plate is then washed with a solution of gum in weak phosphoric acid which readily wets the 'bitten' portions, but is repelled by the grease of the printing. A lithographic inking-roller is then brought over the zinc plate, the ink being taken up by the greasy printed parts only, and an impression is obtained in the ordinary lithographic press. *Paneiconography* (Gr. *pan*, 'all,' *eikōn*, 'an image,' and *graphō*, 'I write'), invented by Gillot, of Paris, is a process of producing a design in relief on a zinc plate adapted for printing in a typographical press. The design is either executed in lithographic crayon or ink by the artist, or a fresh impression of a lithograph, woodcut, or copperplate engraving is transferred to the zinc plate. The design is again inked, and powdered rosin dusted over it. The zinc plate is then submitted to the action of dilute hydrochloric or sulphuric acid, which eats away and lowers the portions of the plate unprotected by rosin. The operations of inking, dusting with rosin, and etching are repeated till sufficient relief of the design is obtained.

Zin'gel (*Aspro zingel*), a species of *Teleostean* fish allied to the Perch (q. v.), and found in the Danube and some other European rivers. The body is long, and the mouth is placed under the snout There are two discontinuous dorsal fins, and the others are large. The average length of the fish is 12 inches. Another species (*A. vulgaris*) inhabits the Rhone. Both kinds are very palatable.

Zingibera'ceæ, an order of monocotyledons, considered by some as a sub-order of Scitamineæ, and distinguished from both Musaceæ and Marantaceæ by the stamens (of which one only is perfect) bearing a two-celled anther. The species are exclusively tropical, aromatic, with creeping root-stock, large simple handsome flowers, forming either a dense spike or a branched panicle. Zingiber, Curcuma, Amomum, Alpinia, and Costus are among the more noted of the thirty or forty genera of Z.

Zinz'endorf und Pott'endorf, Nikolaus Ludwig Graf von, a name eminent in the religious history of Germany, was born at Dresden, 26th May 1700. He studied law and theology at Wittenberg (1716), resided abroad for some years (1719–20), gave himself up to evangelical labours, and founded on his estate of Berthelsdorf a religious community, chiefly consisting of men who had been driven out of Bohemia and Moravia on account of their religious opinions (1723). This community was called Herrnhut ('protected of God'), and it soon attracted great attention in Germany from the zeal of its members, the high position of Z., and the constant intermeddling of church and state with its affairs. Z. qualified himself for the pastoral office, and in 1737, at Berlin, was consecrated as bishop with the sanction of the government. This, however, seems to have roused his enemies to fresh efforts, for shortly after the government condemned him to perpetual banishment as a religious innovator, and Z. was obliged to leave Saxony. In 1747 he was permitted to return and resume his labours. He died 9th May 1760, at Herrnhut. Z. held the usual 'orthodox' Protestant views with but little modification, but he held them with the fullest concession of the right of free opinion to others. He was an earnest, sincere, and noble man. His writings, among which were several collections of 'hymns,' were entirely of a religious character. See the Lives of Z. by Spangenberg (8 vols. Barby 1772-75), Bovet (3d ed. Par. 1865; trans. by Gill, Lond. 1865), and Burkhardt (Gotha 1866); Korner, *Die Kursachsische Staatsregierung dem Grafen Z. und Herrnhut bis* 1760 *gegenuber* (Leip. 1878); and Plitt, *Pottendorfs Theologie* (3 vols. Gotha 1869–74).

Zi'on. See JERUSALEM.

Ziph'ius, a genus of Whales (q. v.) belonging to the family of the *Rhynchoceti*, or 'Beaked whales. Z. occurs in the Mediterranean Sea and S. Atlantic. The snout is pointed, there is a single blow-hole, and a small dorsal fin is developed. There are no teeth in the upper jaw, but the lower jaw is provided with from 1 to 2 pairs. *Z. Sowerbiensis* is a familiar species. The average length is 16 feet.

Zirco'nia Light, an intensely brilliant light differing from the Drummond Light (q. v.) mainly in the employment of cones of the oxide of zirconium instead of the less durable cylinders of lime. In 1867 Tessié du Motay introduced the Z. L. into Paris, and it was there employed for several years to illuminate squares and public buildings and gardens. The cones were formed of burnt zirconia kneaded into a paste with aqueous boracic acid, and hardened in iron moulds at a red heat, and a mixture of oxygen and a highly carburetted gas was burnt to raise the cones to incandescence. The Z. L. was also some time used as an illuminant in public places of Brussels and Vienna, and in America in lighthouses and public works. The construction of the Brooklyn Bridge over East River, New York, was conducted by night under the radiant light from zircon cones acted on by oxygen. The Z. L. has been practically superseded by the Electric Light (q. v.)

Zirco'nium (Zr=89·6), a somewhat rare metal, intermediate in many of its properties to aluminium and silicium. Its oxide, zirconia, was first prepared by Klaproth in 1789 from the mineral zircon, which is essentially a silicate of Z., and is found crystallised in square prismatic or octahedric crystals. Eudialyte, wöherite, fergusonite, and a few other rare minerals also contain small quantities of Z. Like silicum, this metal exists in three allotropic conditions, amorphous, crystalline, and graphitoidal. It burns in air only at the temperature of the oxyhydrogen flame, but ignites in chlorine gas at a red heat. It is affected slightly by ordinary acids, though readily attached by hydrofluoric acid evolving hydrogen. Zirconia (ZrO_2) is prepared by fusing zircon with four times its mass of dry sodium carbonate with a little sodium hydrate, treating with hydrochloric acid to dissolve out the silica, and precipitating the impure zirconia by the addition of ammonia. When purified it forms a white powder, or hard lumps of specific gravity 4·35 to 4·9. It forms two hydrates, having the compositions ZrO_3H_2 and $ZrO_2 \cdot 2H_2O$. Zirconia acts both as a base and an acid, but after ignition is acted upon only by hydrofluoric or strong sulphuric acid. The fluoride (ZrF_4) unites with other metallic fluorides forming zircofluorides which are isomorphous with the corresponding silicofluorides, stannofluorides, and titanofluorides.

Zirk'nitz, a lake of Austria, 30 miles E.N.E. of Trieste, is 5 miles long, 3 broad, and 60 feet deep. It is chiefly remarkable for the fact that at irregular intervals its waters wholly disappear through fissures in its limestone bed which communi-

cate with cavernous reservoirs below. There are four islands in the lake—one peopled—and numerous villages on the shore. The usual time of disappearance is August; the return of the water occurs suddenly, and usually in September. Sometimes the lake remains undrained for five or six years. Once, in 1834-35, it was dry for fourteen months continuously.

Zis'ka (pron. *Shishka*) **of Trocnow, John,** the Hussite leader, was born of noble parents about 1360 at Trocnow, in the Budweis district of Bohemia. Though he had lost his left eye when a boy, he spent his youth as a page at the court of King Wenceslaus, in 1410 joined the troops that marched from Bohemia and Hungary to help the Teutonic knights against the Poles and Lithuanians, and took part in the battle of Tannenberg (15th July). After this he fought in the campaigns of the Hungarians against the Turks, and on the side of the English against the French, especially distinguishing himself at Agincourt (1415). On his return to Bohemia, he attached himself to the extreme party of the Hussites, who under his leadership quickly became trained soldiers, and learned to fortify their camps by 'Wagenburgen,' *i.e.*, waggons so placed as to form defensive squares. In 1421 he founded a fortress on Mount Tabor, on the 14th July of that year he defeated the German crusading army on the mountain ever since called *Ziskaberg*, and in January 1422 he decisively defeated Siegmund in the battle of Böhmisch-Brod. At the head of the Taborites, Z. now advanced against the moderate Calixtines, whose possessions he ravaged in the most wanton manner. Though at the siege of the Castle of Raby in 1421 he had lost his second eye, he still continued not only to order the march, following his officers' descriptions of the ground, but to direct in battle his 'invincible legion of brothers.' The Emperor had already begun to despair of success in the contest, and had opened negotiations with Z., promising full liberty of conscience, when the latter died, during the siege of Przibislaw, October 11, 1424. He was buried in the Church of SS. Peter and Paul at Czaslau, with his battle-axe suspended above his grave. In 1623 the tomb was opened by imperial command, and his bones were removed to Vienna. Z. was an able commander, quick in thought and action, of great presence of mind, and of iron firmness, a merciless opponent of the enemies of his country and his faith. See HUSSITES, and Millauer, *Diplomatisch-historische Aufsätze über John Z. v. T.* (Prague 1824).

Zittau' (orig. *Sittower*, 'corn town'), a town of Saxony, on the Niesse, 71 miles E.S.E. of Dresden by rail. It has a magnificent Rathhaus (1844), the Church of St. John (1836) in the Byzantine style, 6 other Protestant churches and 1 Catholic, a gymnasium, and other excellent schools, and is surrounded by fortifications. A great seat of cotton manufacture, Z. has also linen, paper, and saw mills, and some iron foundries. Coal is found in the vicinity. Pop. (1875) 20,417. A frontier town, Z. was almost destroyed by an Austrian bombardment in 1757, but has long had an active trade. For a notice of its interesting history see Peschek's *Handbuch der Geschichte von Z.* (Zitt. 1835-38).

Zlatoust' or **Slatoust'**, a town of Russia, government of Ufa, on the Ai, an affluent of the river Ufa, and near the Ural Mountains, 150 miles N.E. of Ufa. In the vicinity are rich iron and gold mines. Z. manufactures sword-blades and other steel fabrics. Pop. (*St. Petersb. Cal.* for 1878) 16,629.

Zmein'ogorsk (Russ. 'snake mountain'), a mining town of Asiatic Russia, in the government of Tomsk, with silver, copper, lead, and iron mines. Its silver-smelting furnaces turn out about 3½ tons of silver annually. Pop. (1870) 14,904.

Znaim (Czech. *Znojem*), a town of Moravia, Austria, on the Thaya, 50 miles N. by W. of Vienna by rail. It has a Rathhaus (1446), a circular church, said to have been a heathen temple, and the Gothic Church of St. Nicolas. The old ducal castle crowns a neighbouring height. The trade is largely agricultural. Mustard, wine, and cucumbers are exported, and there are large potteries, at which fine Majolica is produced. Leather and chocolate are also manufactured. New waterworks were opened in 1877. Pop. (1869) 10,415. Formerly *Znoimo*, under which name it was the capital of Moravia, Z. was destroyed in 1145 by the Bohemian prince Vladislav, but was rebuilt in 1226. On 11th July 1809 the French under Massena and Marmont defeated the Austrians here, and from 13th July to 3d September 1866 it was held by the Prussians. See Hübner's *Denkwürdigkeiten der Stadt Z.* (Znaim 1869).

Zoar, a village of Ohio, U.S., settled in 1817 by Germans, on a communistic basis. The Society of Separatists of Z. hold nearly 8000 acres, and a board of trustees manage their business. Pop. (1780) 326. See *Communistic Society of the United States*, by Charles Nordhoff (Lond. 1875).

Zoanthar'ia, an order of *Actinozoa* (q. v.) in which the sea anemones and most of the corals are contained. The tentacles and soft parts exist in multiples of 5 or 6. The Z. are divided into the *Z. malacodermata* (sea-anemones, &c.), *Z. sclerobasica* (*Antipathes*), and *Z. sclerodermata* (reef-building corals).

Zo'diac is the name given to the imaginary zone in the heavens, which extends about 8° or 9° on each side of the ecliptic. It is divided into twelve regions or *signs*, each of which is occupied by the sun during a particular month of the year, and which retain the names of the constellations with which they were originally identical. The names of these signs are Aries, Taurus, Gemini, Cancer, Leo, Virgo, Libra, Scorpio, Sagittarius, Capricornus, Aquarius, Pisces. The sun enters Aries at the spring equinox, and Libra at the autumnal equinox, while the first points of Cancer and Capricornus mark the summer and winter solstices respectively. In consequence of the precession of the equinoxes, the constellations corresponding in name with the signs of the Z. and originally coincident with them have moved along the ecliptic in the direction of the sun's motion, so that the *sign* Aries coincides at present with the *constellation* Pisces. Astronomically, the Z. is of no practical value; its chief interest is historical. Though the name is Greek in origin, being derived from *zōdion*, a diminutive of *zōon*, an animal, and so employed because of the preponderance of animal figures among the signs, the real origin of this division of the sun's apparent path in the heavens dates from a much earlier period than that in which the Greek school of astronomy flourished. On the ceilings of portions of the ancient temples of Denderah and Esne in Egypt, symbolic representation of the signs is still to be seen; and evidence exists to show that among the Persians, Hindus, Chinese, and Japanese a similar division of the Z. has long been used. More recently Rawlinson has found in the lately discovered library of Sardanapalus at Nineveh interesting notices concerning the Z., including an epic poem upon the twelve month-adventures of Izduhar, the hero of the sun, which is simply a poetical account of the zodiacal signs. The general similarity of the Z. as existing in the different nations of antiquity points to the strong probability that these have derived their knowledge from one original source, and that present discrepancies are the result of subsequent departures from the first Z. forms.

Zodi'acal Light, a cone-shaped luminosity which appears at certain times of the year either after sunset in the west or before sunrise in the east. The axis of the cone lies in the sun's equatorial plane, so that the phenomenon appears confined within the limits of the zodiac, hence the name. At the vernal equinox, the Z. L. appears as a pyramidal body of light, broad and bright at its horizon base, but fading gradually as it tapers up towards the Pleiades. In the tropics its brilliancy is very marked, rivalling at times the Milky Way; but in temperate latitudes it is to be seen only on favourable evenings. Of late years the Z. L. has been seen to best advantage not at the equinoxes but at a somewhat later date, a fact which suggests a precessional motion, if, as is most probable, the Z. L. be a solar appendage. The first recorded observation of the phenomenon is by Childrey in 1660; but Dominico Cassini (1683) was the first to make careful measurement of its dimensions. He suggested that it might be due to the blended light of innumerable minute planets circulating round the sun; Euler speculated upon the probability of its identity with comets; Mairan and others regarded it as the solar atmosphere, a hypothesis which Laplace proved to be untenable; Schubert, Laplace, and Poisson believed it to be a nebular ring revolving planet-fashion round the sun; Sir John Herschel conjectured that it was simply a denser region of the interplanetary medium, 'loaded perhaps with the actual material of the tails' of comets; later speculators have striven to establish a terrestrial origin; but, perhaps, the most plausible of all hypotheses is that supported

by Sir W. Thomson, which regards the Z. L. as the glow from a cloud of meteors circulating round the sun. Taken in conjunction with the established laws of meteor streams and Tait's 'sea-bird' theory of Comets (q. v.), this hypothesis not only can be made to account for all the peculiarities of the Z. L., but is remarkable as combining in one the early theories of Cassini and Euler.

Zo'ilus, a Greek rhetor, said to have been a native of Amphipolis in Thrace, flourished in the 3d or 4th c. B.C. The scanty notices of him in scholiasts and others do not always agree, and as nothing he wrote has survived, we can form no secure opinion of his real character as a critic. Antiquity, however, seems to have been unanimous as to his bitter hostility to Homer, on account of which he was called *Homeromastix* ('the scourge of Homer'). His name has in consequence become a symbol for any rancorous critic. 'Every great poet has his Z.'

Zo'la, Émile, born in Paris, 2d April 1840, is the son of an Italian engineer. Bred in Provence and educated at the Parisian Lycée Saint-Louis, he turned from bookseller a novelist, producing *Contes à Ninon* (1864), *La Confession de Claude* (1865), *Le Voeu d'une Morte* (1866), *Les Mystères de Marseille* (1867), &c., titles that indicate the scope of one who may fairly be called a realist of the foulest water. An immense success has attended his series, *Les Rougon-Macquart, histoire naturelle et sociale d'une famille sous le second Empire* (7 vols. 1874–77), the last volume of which, *L'Assommoir*, was dramatised by Charles Reade under the title *Drink* (1879). Z. himself brought out two comedies, *Club* and *Le Bouton de Rose*, in 1878, with small success; his latest work is *La République et la Littérature* (1879).

Zoll'verein (Ger. 'customs-union') was a union for certain fiscal purposes of the smaller German States under the leadership of Prussia. The need for such a union was long felt, for it is easy to imagine how utterly ruinous to commerce it must have been to be obliged to cross a frontier every few miles. The purpose of the Z. was to enable all the contracting states to act for certain purposes as one. All imports were collected on a common frontier, and the funds thus received were divided among the states in proportion to their several populations. The necessity of a Z. was acknowledged at the reconstruction of Germany after the final fall of Napoleon. Prussia so quickly growing into dominion, took the lead in a series of commercial measures (20th May 1818), and by a succession of treaties and agreements, renewed from time to time, by far the greater proportion of the German states became incorporated in the union. The affairs were managed by a *Zollbundesrath*, or council of delegates from the covenanting states, and a *Zollparliament*, or assemblage of those chosen by popular election. These were of course done away with when the modern German Empire was founded. By the 33d article of the Constitution (16th April 1871), the whole of Germany, except Bremen and Hamburg, is included in one common system of duties. The Z. was a step, though a very humble one, towards the great end of German unity. See Weber, *Der Deutsche Z., Geschichte seiner Entstehung und Entwickelung* (2d ed. Leip. 1871).

Zom'bor (Sombor), a town of the Hungarian comitat, Bács-Bodrog, on the Baczer or Franzens Canal, which unites the Theiss with the Danube, and 65 miles S.W. of Szegedin by rail. It has two Greek churches, a magnificent town-house, and a public library, and carries on manufactures of silk. There is a large trade in cattle and corn. Pop. (1869) 24,309.

Zona'ras, Joannes, a Byzantine writer of the 12th c. A.D., born at Constantinople, held various high offices at the courts of Alexius and Joannes Comnenus, but afterwards withdrew to a monastery on Mount Athos, where he died at the age of eighty-eight. His *Chronicon*, from the creation to 1118 A.D., is valuable as preserving many fragments of perished histories, and was last edited by Dindorf (6 vols. Leip. 1868–75), and his Commentaries were edited by Beveridge (Oxf. 1672). He was also the reputed author of several other works, among them a Greek Lexicon (ed. by Tittman, 2 vols. Leip. 1808.

Zonu'ridæ, a family of *Lacertilia* (q. v.) or Lizards, in which the limbs may be well developed or altogether wanting. There is a longitudinal fold of skin on the sides of the body, and the scales of the abdomen are square or rounded in form, and are disposed in zones or bands—hence the origin of the name Z. Distinct ears and eyelids are developed. The *Ophisaurus* or Glass Snake of America, and the *Pseudopi* or *Sheltopusiks* of the Old World, represent the family.

Zo'öids (Gr.), the name given to the beings produced by asexual processes of *gemmation*, or budding, or by *fission*. The Z. collectively make up a compound 'individual'—as for example in a Zoophyte (q. v.), where the whole organism, including its hundreds of animals, is an 'individual' animal, its constituent elements being named '*zoöids*.'

Zool'ogy (Gr. *zōon*, an 'animal,' and *logia*, a 'discourse' or 'scientific account'), the department of *Biology* (q. v.) which deals with the structure, physiology, and distribution of the animal world. Under this head also the details of *Comparative Anatomy* are investigated. The following divisions enter into the principles of zoological study :—

I. *Morphology.* (Science of Form)	(*a*) Anatomy. (*b*) Development. (*c*) Taxonomy.
II. *Physiology.* (Science of Function.)	(*a*) Function of Nutrition. (*b*) Function of Reproduction. (*c*) Function of Correlation or Irritability.
III. *Distribution.*	(*a*) In Space (Geographical). (*b*) In Time (Geological).

We find, firstly, a science which deals with the form and structure of the organism, and this we term Morphology. Secondly, we have the science of function—Physiology. And lastly, we have the Distributional aspect of the science, by which we ascertain the habitat of an animal, or the conditions in which it exists with regard to the external world. It is further to be observed, that each of these primary sections is divided into subsidiary branches. Thus under the head of Morphology, we have *Anatomy, Development*, and *Taxonomy*, each subdivision dealing with a separate aspect of the main science; and we shall now endeavour to explain the object of each section. We may, firstly, study an animal morphologically; that is, consider its form and structure. Under this head we observe its various structural features. By *Anatomy* we investigate its external and internal appearances, the positions and relations of organs and parts. We thus obtain a knowledge of its structure as a fully-formed being. But if we wish to study it through the various stages leading from the embryonic to the mature and adult state, we must call to aid the second department of morphological science, and consider the subject of *Development*. From these, we pass by an easy transition to the consideration of its place in the scale of life, and for which task our knowledge of its structure has fully prepared us. We thus include the third division, that of *Taxonomy* or *Classification*. Having investigated the structural relations of the animal, we next proceed to inquire into its *Physiology* or the study of its *Functions*. Of these, the first is the function of *nutrition*, through which the animal nourishes itself; secondly, we find the function of *reproduction*, through which the *species or race* is maintained; and thirdly, the function of *innervation*, or that of the nervous system, through which the animal maintains relations with the external world. The third and last division of biology is that of *Distribution*. By this branch we determine the place an animal occupies in the globe at the present time, or the conditions under which it existed in times past. The former aspect deals with the *geographical* distribution of the organism; the latter investigates its *geological* relations. Thus the Marsupial or Pouched Mammals, represented by the kangaroos and their allies, occupy a very limited geographical area, being almost entirely confined to Australia, whilst their geological relations present many features of similar import and interest. In this way the modern study of Z. is prosecuted, some authorities adding a fourth head, that of *Etiology*, to the three preceding sections. Through *Etiology*, the *descent* and *origin* of animals are investigated, this department dealing with the evolutionary aspects of zoological science. The modern arrangement of the animal world is based on the discovery of *morphological types*, or *sub-kingdoms* of animals, which are usually ranked as follows :—(1) *Protozoa* (q. v.), (2) *Cælenterata* (see HYDROZOA), (3) *Echinozoa* or *Annuloida* (q. v.), (4) *Annulosa* or *Articulata* (q.v.), (5) *Mollusca* (q. v.), and (6) *Vertebrata* (q. v.).

Zo'ophyte (Gr. *zōon*, an 'animal,' and *phyton*, a 'plant'), the name used generally, in zoology, to denote those compound colonies of animals which grow in the striking likeness of plants,

but limited in scientific strictness to the plant-like members of the class *Hydrozoa* (*Cœlenterata*). The *Sertularians* or sea-firs and the *Flustræ* or sea-mats, included in the class *Polyzoa* (q.v.) of the Mollusca, are good examples of the Z. The Z. consists of a colony of animals, produced by a process of *continuous gemmation* or *budding*, but it can also propagate its species by means of *ova* or eggs. The ova lay the foundations of new colonies.

Zo'ospore (Gr. *zōos*, 'living,' and *spora*, 'a seed'), or **Swarmspores**, are bodies found in cellular cryptogams endowed with a remarkable spontaneous power of motion. They occur, for instance, in fresh water and marine *Algæ*. After breaking free as microscopic particles of protoplasm from the particular cell of the parent plant in which they have been formed, they swim about like Infusoria by means of vibratile cilia for a longer or a shorter time, gradually settling to rest, when a cell-wall of cellulose is developed, and they grow into new individual plants. It was by the observation of this reproduction that Z. were finally removed from the animal kingdom.

Zoot'oca (Gr. *zōotokos*, 'producing young alive'), a genus of lizards included in the family *Lacertidæ*, and represented by the *Z. vivipara*, the Viviparous or Scaly lizard, which, with the *Lacerta agilis* or Sand lizard, are the only members of the Lizard group inhabiting Britain. The viviparous lizard is common on heaths and in grassy places. It attains a length of 6 inches; the colour is olive-brown above, with a dark line passing along the spine. The under parts are orange, marked with black in the male, and olive-brown in the female.

Zoroas'ter (more properly **Zarath'ustra**, in modern Persian **Zerdusht'**), the founder of the religious system contained in the Zend-Avesta (q. v.), now professed only by the Parsees or fire-worshippers of Western India. The derivation of the name is uncertain; but it probably means 'elder' or 'priest,' and as such is identified with the author of the sacred books or Zend-Avesta, which have evidently been composed at different periods. That Z. was an historical personage, equally with Buddha, Confucius, and Mahomet, it is impossible to doubt; but the traditional accounts of his life are absolutely untrustworthy. We only know that his family name was Spitami, and that he was born in Bactria, near the modern Balkh. The best authorities place him in the 10th c. B.C. In all likelihood, it was under his reforming influence that his Iranian countrymen were induced to separate from the common Aryan stock, taking with them a religion that still shows traces of the nature-worship of the Vedas, and a language that is most nearly akin to the primitive Sanskrit. This religion, contrary to vulgar opinion, does not possess as essential characteristics either dualism between the powers of good and evil, or fire-worship, or the study of astronomy. It may be more truly described as pure monotheism, expressed in elaborate rules of ceremonial observance. Fire-worship is probably a relic of the natural mythology of the primitive Aryan faith, and dualism is a philosophical conception of comparatively recent growth. So far as we are able to distinguish the original matter from later accretions, the sum total of Z.'s teaching is the belief in Ahura Mazdao, Auramazda or Ormuzd (q. v.), 'the source of light,' as opposed to the many *devas* or gods of the Sanskrit-speaking Hindus. See *Essays on the Sacred Language, Writings, and Religion of the Parsees*, by Martin Haug (Bomb. 1862); Spiegel, *Erânische Alterthumskunde* (3 vols. Leip. 1871–78); and Darmesteter, *Ormazd et Ahriman* (Par. 1877).

Zorn'dorf, a village in Brandenburg, Prussia, 4 miles N. of Küstrin, famous as the scene of a desperate battle in the Seven Years' War between 50,000 Russians under Fermor and 30,000 Prussians under Friedrich the Great, August 15, 1758. The Russians were defeated with a loss of 20,000 men; the victors lost 13,000.

Zos'imus, a Greek, succeeded Innocent I. as Bishop of Rome, A.D. 417. He deserves notice only for the partial countenance he gave to the Pelagian doctrines, as they were expounded to him by their author's disciple, Cœlestius. The council of Carthage, however (418), reaffirmed the unsoundness of Pelagius, and this judgment soon received the hearty assent of Z. His letters on this matter, and on Gaulish affairs, may be found in Coustant's *Epistolæ Romanorum Pontificum* (Par. 1721). Z. died December 26, 418.

Zos'imus, of Constantinople, is supposed to have held office there as advocate to the treasury. He wrote a *History of the Roman Emperors*, from Augustus to 410 A.D. In this work, which, is ably executed, he inveighs bitterly against the Christian emperors, particularly Constantine and Theodosius I. The best edition of Z. is that of Bekker (Bonn, 1837), forming a volume of Niebuhr's *Corpus Scriptorum Historiæ Byzantinæ*. An English translation of the history appeared in 1814 (Military Library).

Zouaves' (Arab. *Zwava*), a body of French infantry, deriving their name from a tribe of Algerian Kabyles, whose fighting men were famous throughout N. Africa for centuries. After the French occupation of Algiers in 1830, a body of these Kabyles, who had been employed as mercenaries by the Dey, were incorporated with the French army and provided with French officers and arms. The Arab dress was preserved, but Frenchmen were distributed among the companies as private soldiers. Subsequently the corps was formed into distinct French and Arab companies, and in 1837 it was divided into three battalions under Lamoricière, to whom, and to General Cavaignac, was due its singular efficiency in the final conquest of Algeria. But long before the French supremacy was complete, it had been found necessary to eliminate the native element from the Zouave corps, and after 1840 the Z. were simply European troops retaining the old name and dress. These troops were the *élite* of the French infantry during the Crimean War, and revived their old reputation in the Italian campaign of 1859. On the reorganisation of the army, under the law of March 13, 1875, the Z. were divided into four regiments, each of four battalions, and containing in all 16,000 men. Three of the regiments are in the 19th army corps in Algeria. They are armed with carbines and short sword-bayonets, and their dress is a loose dark blue jacket and waistcoat and Turkish trousers, red fez with yellow tassel, sky-blue sash, yellow leather leggings, and white gaiters. During the American Civil War a few volunteer regiments took the name and dress of the Z., and militia regiments in the States also bear the name.

Zschokk'e, Johann Heinrich Daniel, German playwright, historian, and novelist, born at Magdeburg, 22d March 1771, studied theology, philosophy, history, and literature at the university of Frankfurt, and acted till 1795 as a *privat-docent* there; travelled over a considerable part of Europe, finally settled as schoolmaster in Switzerland, where he greatly distinguished himself during the revolutionary troubles by his efforts on behalf of his adopted country, was appointed to several high public positions, spent the last years of his life in continuous literary activity, and died at Aarau, 27th June 1848. Z. was a very prolific author. He wrote *Abällino, der Grosse Bandit* (Berl. 1793), a drama of the then popular 'blood and thunder' character, a number of works on the history and forestry of Switzerland, *Stunden der Andacht* (29th ed. Frankf. 1853, new ed. 1873; translation by Burrows, Lond. 1830), a highly popular book of devotion written from a rationalistic standpoint, and a large number of very excellent novels, distinguished by lively humour, considerable powers of description, and clever construction and development of plot. Among these last *Jonathan Frock*, *Die Neujahrsnacht*, and *Das Goldmacherdorf* (Eng. trans. Lond. 1845) deserve special mention. There is an English translation of his *Tales* by Godwin (2 vols. Lond. 1846). See Z.'s *Sämmtliche Schriften* (40 vols. 2d ed. Aarau 1856 and following), and Emil Zschokke's *Z.* (3d ed. Berl. 1876).

Zschop'au, a town of Saxony, government of Zwickau, on the river Z., an affluent of the Mulda, and 26 miles E. of the town of Zwickau. It has a castle built on the top of a rock, and important woollen and cotton manufactures. Pop. (1875) 8045.

Zucc'aro, Federi'go, an Italian painter, born in 1543, was intrusted by Pope Gregory XIII. with the completion of the pictures in the Pauline Chapel, begun by Raphael. Falling into disgrace, however, he went abroad, and spent several years in Flanders, Holland, and England, where he painted portraits, among others, those of Queen Elizabeth and Mary Stuart. In 1582 he was employed in adorning with pictures the palace of the Doge of Venice. He founded the Academy of San-Luca, was called to Spain in 1588 to decorate the Escurial, but soon returned to Italy, where he died in 1609. Both Federigo and his brother Taddeo (born 1529, died 1566), in spite of their artistic merits, are examples of the decadence of Italian art in the latter half of the 16th c., of its lack of originality, genuineness, and power.

Zug, the smallest of the Swiss cantons, lies near the centre of Switzerland, and is bounded on the N. by Zürich, on the W. by Luzern and Aargau, and on the S. and E. by Schwyz. Area, 92 sq. miles; pop. (1877) 21,915, of which only 4 per cent. are Protestant. One-seventh of the canton consists of lake. From the Ægerisee, near the eastern shore of which lies the famous Morgarten pass, the scene of the Austrian defeat in 1315, the river Lorze flows N.W. to the northern extremity of the Zugersee, thence continuing its course northward to the Reuss. The Zugersee is a picturesque lake, 9 miles long and 2 or 3 miles broad, which extends in a N. and S. direction at the base of orchard-clad and beautifully wooded heights of moderate elevation. The highest peak is the Rossberg, which is 6045 feet above the sea-level, and 4445 feet above the lake. The soil throughout the canton is fertile and the climate mild, chestnuts and figs even ripening in the open air. Pasturage is excellent, and cattle, butter, cheese, and condensed milk (manufactured since 1867 at Cham, a village at the north end of the Zugersee) are among the exports. Other exports are honey, dried fruit, cider, cereals, kirschenwasser, and cotton goods. Silk-weaving also forms an important industry, and paper manufactures exist at Baar and Cham. Fish abound in the lakes. See Egli's *Taschenbuch Schweizerischer Geographie, Volkswirthschaft und Kulturgeschichte* (2d ed. 1878).

Zug, the capital of the canton of Z., lies on the N.E. shore of the Zugersee, at the base of the orchard-clad Zugerberg (3251 feet). It has manufactures of kirschenwasser, cider, and paper, and 6 churches, of which the finest are St. Oswald, with a fantastically decorated portal, and St. Michael, standing boldly above the town. There are also a Capuchin and a Franciscan monastery, an arsenal with a collection of weapons of rare historic interest, an hospital, and new government buildings in the Renaissance style. Pop. (1870) 4277.

Zulu' ('heavens'), or **Amazulu** ('people of the heavens'), the leading section of the Kaffir (q. v.) race of S.E. Africa. At the beginning of the present century, the tribe to which the name of Z. more strictly belonged was weak, insignificant, and tributary to the Umtetwa, a powerful tribe occupying the southern portion of what is now known as Zululand (q. v.). Godongwana, a son of the Umtetwa chief, having intrigued against his father, was forced to flee to Cape Town, whence he returned after his father's death, slew his brother, and succeeded him in the sovereignty. This man, henceforward known as Dingiswayo, or 'The Wanderer,' founded among his people a military organisation based upon that which he had seen in Cape Colony, and by means of it speedily conquered the neighbouring tribes. Among the common soldiers in his army was a young man named Utyaka, or Chaka, the illegitimate son of the Z. chief, from whom he had fled to Dingiswayo for refuge. He displayed remarkable military skill and valour, as a reward for which, on his father's death in 1810, Dingiswayo made him chief of the Z. Improving upon the military system of his patron, Chaka entered upon a career of conquest, remaining faithful to Dingiswayo, however, till (about 1818) the latter was captured and killed by a chief whose life he had once spared. Despising the comparatively merciful policy of Dingiswayo, Chaka gave his foes a choice only between submission and extermination, in cases of resistance killing men, women, and children alike, carrying off the cattle and burning the dwellings. In this way he established his sway over the entire region from King George's River, N. of Delagoa Bay, to the St. John's River in Kaffraria, and inland so as to include much of what now forms the Orange River Free State and Transvaal Territory. As a consequence of his conquests, the name Z. ceased to be a merely tribal, and became a national designation. At the same time great changes were wrought in the distribution of the tribes, some of the largest of which were displaced and fled to new regions. Thus the Amafengu, or Fingoes, fled from Natal to Kaffraria, and another large tribe took refuge near the present site of Pretoria (q. v.). The latter, fleeing again from Chaka's successor, eventually settled in the highlands between the Limpopo and Zambesi rivers, and founded the Matebele kingdom of the afterwards notorious king Moselekatse. While still pursuing his victorious career, Chaka was assassinated, September 23, 1828, aged forty-one. As illustrating the bloodthirstiness of his character, it will suffice to mention that, to secure himself on the throne, he ordered all his children to be killed, and with his own hand he stabbed his mother to the heart for sparing one of them alive. He was succeeded by his brother Dingaan, who followed in his footsteps, until in 1838 he came in contact with a new and formidable enemy in the person of the Boers (q. v.), who had come to settle in Natal. By treachery he murdered their leaders, and then surprised and slew the rest of their party to the number of 600 (women and children included), at a place thenceforth known by the name of Weenen, *i.e.*, 'weeping.' Some months later the Boers under Pretorius defeated Dingaan with enormous loss at the Blood River, and in 1840 he died, and was succeeded by his brother Umpande, or Panda. The latter pursued a peaceful policy, and lived on good terms with the British till his death at the end of 1872. In 1854, to settle disputes between his sons Umbulazi and Cetywayo (pron. Ketchwayo) regarding the succession, he allowed them to meet each other in the battlefield, when the former was slain. Cetywayo acted as regent for several years before his father's death, and in 1873 he was formally crowned king by an official representing the Natal Government. He early manifested a desire to imitate his uncles Chaka and Dingaan rather than the peaceful example of his father, but although he perpetrated fearful atrocities upon his subjects, war between him and the British did not break out till January 1879. On the 22d of that month a British camp at Isandhlwana was overpowered by 20,000 Zulus, and 823 Europeans, of whom 49 were officers, besides fully 500 of a native contingent, were killed. Throughout the succeeding night a British post at Rorke's Drift, a few miles distant, was successfully defended against 3000 Zulus by a British force numbering only 139, of whom 17 were killed and 10 wounded, while the Z. loss in killed alone exceeded 350. On March 28th an attack made on the Z. position on the Zlobane Hill by the column on the Transvaal frontier, commanded by Colonel Wood, was repulsed with considerable loss. Next day Colonel Wood's entrenched camp at Kambula Kop was attacked by a Z. force estimated to number 20,000, but after severe fighting the Zulus were routed with a loss reckoned at 2500. On April 2d the main British army under Lord Chelmsford, while advancing to the relief of a British force commanded by Colonel Pearson, which had been beleaguered at Ekowe, in the S.E., since the disaster at Isandhlwana, was attacked at Ginghilova. After a sharp fight of an hour and a half the Zulus were defeated with a loss of 750 killed, the casualties on the British side being very trifling, and Ekowe was relieved next morning. On May 30th, Lieutenant-General Sir Garnet Wolseley, who had just been appointed Governor of Natal and the Transvaal, left England to assume the supreme civil and military command in the disturbed region. On June 1st, Prince Louis Napoleon, only son of the late French Emperor, was 'assegaied' by Zulus near Edutu Kraal, in one of those 'surprises' which have proved a fatal feature of the war. The news excited a profound and sympathetic interest in Europe. Meanwhile Lord Chelmsford had advanced on Ulundi, Cetywayo's great military kraal, with a force of over 5000 men, and on the 4th of July inflicted a crushing defeat on the Z. forces. Cetywayo became a fugitive, and after a long hunt was finally captured on the 28th of August in Ngome Forest by Major Marter of the King's Dragoon Guards. Transported to Cape Town, where he landed on the 14th of September, he still (April 1880) remains a State prisoner in Cape Town Castle. The Z. monarchy and military organisation are completely broken up. In September 1879 Sir Garnet Wolseley parcelled out the country among thirteen chiefs, who undertook to govern their territories in accordance with the regulations prescribed by the High Commissioner, and no difficulty has yet (April 1880) arisen in connection with this new settlement of affairs.

At the present time the Zulus are found not only in Zululand, but in Natal, where many thousands took refuge from the tyranny of their king, as well as in Kaffraria and Cape Colony. The northern Matebele kingdom has been already mentioned, while a Z. tribe, known as the Mazitu or Mangoni, has penetrated still farther N., and now inhabits the tableland bordering on the N.W. shore of Lake Nyassa, between 11° and 12° S. lat. Physically the Zulus are a fine race, being tall, well made, athletic, and exceedingly active. Before the breaking up of Cetywayo's power, his army amounted to 50,000 men. When not at war, the Zulus spend their time in hunting, talking (of which they are fond), singing, dancing, smoking, and drinking. The women do all the field work and build the huts, which are made of sticks covered with straw. Every woman

has a hut to herself. Wives are bought with cows, and the number of a man's wives is only limited by his means. As women are forbidden, under pain of death, to touch cows, the operation of milking these is performed by the men. Like all Kaffirs the Zulus have a great dread of witchcraft, their superstitions in regard to which have been a chief cause of the atrocities so frequent in their country. They also believe that men's souls after death pass into the bodies of snakes, and these reptiles are accordingly regarded with the greatest veneration. In Natal Zulus are employed as servants, porters, &c., but comparatively few of them will work on farms or plantations, or at any occupation involving continuous labour. See Farrer's *Zululand and the Zulus: their History, Beliefs, Customs, Military System, Home Life, Legends, &c., and Missions to them* (Lond. 1879), and Lucas' *The Zulus and the British Frontier* (Lond. 1879); also the *Proceedings of the Royal Geographical Society* for March 1879.

Zulu'land adjoins Natal on the N., and is included between 27° 30'-29° 14' S. lat., and 30° 40'-32° 50' E. long. Its extreme length from N. to S. is 125 miles, its greatest breadth from W. to E. 112 miles, and its area about 10,000 sq. miles. The region lying between the northern extremity of St. Lucia Lake and the Portuguese possessions at Delagoa Bay, though formerly included in Z., is now regarded as a distinct territory, known as Amatongaland. Its inhabitants are less warlike than the Zulus, whom they view with small favour. Z. may be divided, physically, into three districts, running parallel to the coast, and known respectively as Lower, Middle, and Upper Z. The first constitutes the coast district, a strip of low-lying land, from 15 to 20 miles wide, thickly wooded and broken up by swamps and lagoons, which are separated from the sea by a rocky range known as the Berea. Of these lagoons by far the largest is St. Lucia Lake, already mentioned, which is 50 miles long, with an average breadth of 12 miles, but only from 3 to 6 feet deep. This region is very hot, and unhealthy for Europeans, especially from February to May, but possesses a very fertile soil, well suited to the growth of sugar, coffee, rice, cotton, arrowroot, tobacco, &c. *Middle Z.* consists of undulating grassy plains, partially wooded, and crossed by mountain ranges about 3000 feet high, clothed with fine forests, and intersected by *kloofs* or gorges, through which the rivers flow to the sea. This portion of the country is exceedingly beautiful, and enjoys a salubrious climate, while it is well adapted alike for stock-raising and agriculture. *Upper Z.*, between which and Middle Z. there intervenes a mountain range, consists of elevated, broken, and wooded country descending from the great Drakenberg chain of mountains, which are from 20 to 30 miles farther W., and are here about 7000 feet high. Cattle and sheep thrive on the pastures of this region, and wheat grows well. The principal rivers of Z. are the White and Black Umvolosi, which unite near the centre of the country; the Umkusi, Uvulu, Umlalazi, Blood, and Tugela. The last two form the boundary between Z. and Natal. None of the rivers of Z. are navigable, and all are liable to great changes of level. In winter, which is the dry season, they dwindle into mere rivulets, while in summer, heavy thunderstorms in the mountains cause them to swell into foaming torrents, often impassable for weeks. As a rule their banks are clothed with thick bush. Z. is believed to be rich in minerals, and gold has been found not far from the Tugela river, but prospecting being strictly forbidden by the king, no thorough examination of the country, with the object of ascertaining its mineral wealth, has been possible. The capital of Z. is Ulundi, which is beautifully situated in a natural amphitheatre 8 miles in diameter, almost exactly in the centre of the country, and not far from the N. bank of the White Umvolosi river. Smaller villages are numerous, and the total pop. of the country is estimated to be about 300,000. For references see previous article.

Zu'mala-Carr'eguy, Don Tomas, a notable Carlist leader, was born of a royalist family at Ormaiztegua, in the Biscayan province of Guipuzcoa, in 1789. He studied law in the University of Pampeluna, but quitted college for the army at the French invasion in 1808. He served under Mina, was made captain in 1813, and in 1822 commanded two battalions of Quesada's 'Army of Faith' against the upholders of the constitution. When absolute monarchy was re-established in 1823 he became lieutenant-colonel, and governor of Ferrol. For a speech in which he declared that after the death of Ferdinand VII. he would only recognise Carlos V. as king, he was tried by court-martial, without incurring any penalty. In 1832 he was dismissed from the army along with other Carlists; but in October 1833 he raised a body of royalist volunteers in the Basque provinces, and next year he was joined by Carlos. He then gained five great victories, one in the valley of the Amescoas, against Rodil (August 1, 1834), another at Viana (September 7), the third on the plains of Vittoria (October), the fourth a brilliant defeat of Valdes in the valley already mentioned (1835), and the fifth the subjugation of Iriarte at Guernica. While in a career of triumph he besieged Bilboa, and there was mortally wounded by a musket ball June 15, 1835, dying at Cezama ten days later. 'Uncle Tomas,' as his devoted soldiers called him, had sacrificed fortune, family, and a heroic life to a prince unworthy of his allegiance. C. F. Henningsen has published *The most Striking Events of a Twelve Months' Campaign with Z.* (2 vols. Lond. 1826).

Zumpt, Karl Gottlob, a well-known classical philologist, was born at Berlin, March 20, 1792, entered the University of Heidelberg in 1809, studied afterwards at Berlin, and became in 1827 extraordinary and in 1836 ordinary professor of Roman literature at the latter. In 1831 he travelled in Italy and in 1835 in Greece. He died at Karlsbad, June 25, 1849. Z. is best known by his *Lat. Grammatik* (Berl. 1818; 13th ed. 1874). His other works are *Annales Veterum Regnorum et Populorum* (1819; 3d ed. 1842); *Ueber den Röm. Ritterstand* (1839); *Ueber den Stand der Bevölkerung und die Volksvermehrung im Alterthum* (1841); *Ueber den Bestand der Philosophischen Schulen in Athen und die Succession der Scholarchen* (1843); *Ueber die bauliche Einrichtung des Röm. Wohnhauses* (1844, 2d ed. 1851); *Die Religion der Römer* (1845); *Ueber die Persönliche Freiheit des Röm. Bürgers und die Gesetzlichen Garantien derselben* (Darmst. 1846); and his editions of Quintilian (Leip. 1831), Curtius (Berl. 1826), and Cicero's *Orationes in Verrem* (2 vols. 1831), and *De Officiis* (Braunsch. 1838). See his nephew's *De C. Tim. Zumptii Vita et Studiis Narratio* (Berl. 1851).—**August Wilhelm Z.**, nephew of the preceding, was born at Königsberg, December 4, 1815, in 1833 entered the University of Berlin, and became in 1851 professor at the Friedrich-Wilhelm gymnasium there. He died at Berlin, April 23, 1877. His chief works are *Commentationes Epigraphicæ* (2 vols. Berl. 1850-54); *Studia Romana* (1859); *Das Kriminalrecht der Röm. Republik* (2 vols. 1865-69); *Das Geburtsjahr Christi* (Leips. 1869); and *Der Kriminalprozess der Röm. Republik* (Berl. 1871). See Padelletti, *A. W. Z., zur Erinnerung an sein Leben und seine Schriften* (Leip. 1878).

Zunz, Leopold, the Nestor of modern Hebrew scholarship, was born at Detmold, 10th August 1794, and after some years in Wolfenbüttel gymnasium, studied philology at Göttingen and Berlin. Preacher at the New Berlin Synagogue (1820-22) and joint-editor of the *Spener'sche Zeitung* (1824-32), he also directed the Jewish school (1825-29), and, after a visit to Prague (1835), the new Normal Seminary (1839-50). In 1845 he became a member of the Commission for the Education of Jews in Prussia. Among his numerous works are *Etwas über die rabbinische Literatur* (1818), *Die Gottesdienstlichen Vorträge der Juden* (1832), *Die synagogale Poesie des Mittelalters* (1855), *Literaturgeschichte der synagogalen Poesie* (1869), &c., republished in his *Gesammelte Schriften* (3 vols Berl. 1875-76).

Zü'rich, one of the N.E. cantons of Switzerland, is bounded on the W. by Aargau, on the S. by Zug and Schwyz, on the E. by St. Gallen and Thurgau, and on the N. by Schaffhausen and the German state of Baden. Area, 665 sq. miles; pop. (1877) 296,815, of which 18,100 are Catholics, 510 Jews, and the rest Protestants. From the somewhat hilly S.E. district culminating in the Schnebelhorn (4249 feet), the surface slopes down towards the N.W., all its lakes and streams draining ultimately into the Rhine, which here partly forms the boundary between Switzerland and Germany. In the S.W. of the canton, beautifully situated at the base of wood-crested ridges, whose gentle slopes display a choice mingling of orchards, vineyards, meadows, and fields, stretches the crescent-shaped Zürichersee, with a length of 25½ miles, a breadth of never more than 2½ miles, and an area of 34 sq. miles. It is fed by the Linth, and is drained by the Limmat, which after receiving the Sihl from the S. flows N.W. to the Aar, a tributary of the Rhine. Of the thirty kinds of fish which are found in the lake, the pike is the most abundant and the salmon trout most prized. To the E. of the northern

extremity of the Zürichersee lies, at a height of 1700 feet, the Pfäffikersee (area, 1¼ sq. miles), from which the Aa flows W. to the Greifensee (area, 3⅝ sq. miles), and is continued under the name of the Glatt N.W. to the Rhine. The Töss, a sister-stream of the Glatt, and lying to the E. of it, and the Thur, which rises in the mountainous region to the S. of the Bodensee and traverses the extreme N.E. portion of the canton, are the only other streams of any importance. The northern half of Z., forming the southern slopes of the valley of the Rhine, is a gently undulating country with wooded ridges and broad fertile valleys, laid out in pleasant meadows and cultivated fields, and studded over with neat and thriving villages. Agriculture is diligently attended to; wine is produced in considerable quantity along the Limmat valley and the flanking slopes of the Zurichersee and in the so-called *Weinland*, embracing portions of the Töss and Thur valleys; and cattle, swine, goats, horses, and sheep are reared throughout the canton. About 200 sq. miles are under forest, but yet to meet the consumption fuel has to be imported. This great demand arises from the peculiar commercial character of the canton, which is the great manufacturing centre of Middle Europe. The cotton manufacture is the most important industry, employing directly nearly 10,000 hands, while taking into account the numerous establishments for dyeing, printing, dressing, and working embroidery, as many as 40,000 hands find employment. In the silk manufacture, which has flourished for three centuries, 4000 are employed in the factories and 18,000 earn a livelihood. The ironworks and machine manufactures, including bell and type founding, are second to none in Switzerland. Paper, clay-ware, leather, soap, and candles are also manufactured in quantity. The exports are silk, cotton, wool, iron, dyes, corn, salt, wood, wine, brandy, hides, and dairy produce.

Zü'rich (the Roman *Turicum*), capital of the canton of Z., and one of the most active industrial and commercial towns of Switzerland, is beautifully situated in a valley between the Uetliberg and Zürichberg, 42¾ miles N.W. of Glarus by rail, at the N.W. end of the Zürichersee, and on the banks of the Limmat, where it issues from the lake in a broad and rapid stream, to be joined a little below the town by the Sihla, which skirts the W. side of Z. The Limmat is crossed by five bridges, and divides the town into two divisions, the Grosse Stadt on its right, and the Kleine Stadt on its left bank. The principal buildings are the Gross-Münster, in the unadorned Romanesque style of the 11th and 12th centuries; the Gothic Frauenmünster, dating from the 13th c.; the Augustinerkirche, used for 300 years as a magazine, but restored to its original purpose in 1848; St. Peterskirche, of which Lavater was pastor for twenty-three years; the Töchterschule, built (1851) on the site of an ancient chapter-house of the 13th c.; the Rathhaus (1689); the Wasserkirche, built in 1479, restored in 1860, now containing the town-library of 40,000 volumes, many Roman antiquities and rare MSS.; the University, founded in 1832 (in 1878 with 87 instructors and 328 students); and the Federal Polytechnic, founded 1861–64. Z. is the chief seat of the industries of the canton, and the emporium of trade for the E. of Switzerland. It manufactures silks, cotton, paper, and machinery. In the district in 1878 the export of silk amounted to £800,000. Pop. (1870) of the town itself, 21,199, with its suburbs, 56,695. See Bluntschli. *Geschichte der Republik Z.* (2 vols. Zür. 1847–48; vol. iii. by Hottinger, 1856).

Züt'phen, a formerly fortified town of the Netherlands, in the province of Gelderland, at the confluence of the Berkel with the Yssel, 18¼ miles N.E. of Arnhem by rail. It has six churches, including the St. Walpurgiskirche of the 12th c., and a gymnasium, manufactures paper, oil, and cement, and carries on considerable trade in wood, corn, and cattle. Pop. (1876) 14,513. Z. was a town in the 10th c., when it was under its own Grafs. Vassals of the Bishop of Utrecht from 1021, they died out in 1107, whereupon Z. fell to the Grafs of Geldern. In the Dutch War of Independence Z., seized by the Patriot party, was taken in 1572 by Alba, who put to death many of its citizens, and in 1586 Sir Philip Sidney was mortally wounded at a skirmish in the neighbourhood. In 1591 Maurice of Orange gained possession of Z. Taken and dismantled by Philippe Duc d'Orleans in 1672, and again taken without opposition by the French in 1795, it yielded its weak garrison of 300 men on the first appearance of the Prussians, 24th November 1813.

Zuy'der Zee' (Dut. 'South Sea'), the largest gulf of the North Sea, on the coast of Holland, is bounded on the E., S., and W. by the provinces North Holland, Utrecht, Gelderland, Overyssel, and Friesland, and separated from the North Sea by the islands Ameland, Terschelling, Vlieland, and Texel. Length, 80 miles; greatest breadth, 40 miles; area, 1365 sq. miles. Within the Z. Z. are the islands Wieringen, Schokland, Urk, and Marken. The Z. Z. receives on the E. the Yssel and on the S. the Amstel, both branches of the Rhine, the latter of which flows into the Ij or Y, a narrow arm of the Z. Z. extending from its S.W. corner, and, with the extension of the Wijkermeer, stretching to the 'neck of Holland,' 4 miles across (see NETHERLANDS). The Z. Z. fisheries in 1875 employed 1282 boats, manned by 3269 men, in the capture of plaice, herrings (24,500,000 caught from October to April), and anchovies (2701 tons, caught chiefly in May and June, and sold for £103,125). The quantity of salted anchovies exported from the Z. Z. in the same year was 1323 tons (56 per cent. to Germany, 8 per cent. to England). The Z. Z. was in early times a lake, called *Flevo* in the Roman period, at a later time *Middelsee*, but from the beginning of the 13th c. to the great flood of 1247 its N.W. shore was gradually engulfed by the sea. The depth of the Z. Z. at its mouth is only 10⅝ feet, and its general depth is 3½ to 26 feet. The part of the Z. Z. south of the islands of Urk and Schokland has an average depth of only 10 feet. The Dutch Government has projected the draining of this part, in area 487,000 acres, an undertaking estimated to occupy twelve to sixteen years, and to cost £10,000,000. It is proposed to build a dyke from Enkhuizen to the mouth of the Yssel, a distance of 28 miles, along the S. side of which powerful steam-pumps will discharge the water from a wide drainage receptacle into the Z. Z., and then to construct a main navigation canal ('Boezem Kanaal') from the Orange locks of the North Sea Canal to the *Ven*, a point 3 miles N. of Enkhuizen, where a harbour will be established that shall be the outport of Amsterdam to the ports of Northern Europe. See *The Z. Z. Reclamation*, in *Engineering* for September 1870; *Revue des Deux Mondes* (November 1875); and Henri Havard, *La Hollande Pittoresque: Voyage aux Villes Mortes au Zuiderzée* (Par. 1875; Eng. trans. 1875).

Zvenigorod'ka, a town of European Russia, in the government of Kiev, on the river Tikitch, 96 miles S.S.E. of the town of Kiev, has numerous sulphur springs in its neighbourhood. Pop. (1870) 11,375.

Zvor'nik, a town of Bosnia, Turkey, on the Drina, 68 miles N.E. of Serajevo. The inhabitants are partly Servian, partly Catholic, and to some extent Mohammedan. The coal and lead mines are rich though undeveloped. Z., which is a fortress of great strength, was occupied by the Russians, 2, in September 1878. Pop. 10,000.

Zwei'brücken (Fr. *Deux-Ponts*), a town of Rhenish Bavaria on the Erbach, here crossed by two bridges, 7 miles S. of Homburg and 35 W. of Landau by rail. It has a Protestant cathedral (1497), an old castle used as a court of justice, and a newly-erected prison. Pop. (1875) 9248. Z. was long the residence of the Dukes of Deux-Ponts or the Z. Palatinate, and here from 1779 were published the well-known *Bipontine Classics*. See Butters' *Ueber die Bipontiner und die Editiones Bipontinæ* (Zweib. 1878).

Zwick'au, a town of Saxony, on the Mulde, 80 miles W.S.W. of Dresden by rail. Its chief buildings are the Gothic Marienkirche (1451; restored 1840), with paintings by Wohlgemuth, an interesting Rathhaus and Exchange of the 16th c., a quondam castle (1581–90), a gymnasium with library, &c. Coal and iron are extensively worked in the neighbourhood; but Z. has also chemical works, saw-mills, tanneries, cotton, and woollen mills. Pop. (1875) 31,491. Z. is first mentioned in 1118, obtained municipal rights in 1212, and until the 17th c. was one of the greatest industrial towns in Saxony. In 1521 it received the Reformation, and became the scene of great Anabaptist struggles. See Herzog's *Chronik der Kreisstadt Z.* (Zwic. 1845), and his *Geschichte des Zwickauer Stein Kohlenbaues* (Dresd. 1852).

Zwing'li, Ulrich, or Huldereich, the famous Swiss reformer, was born January 1, 1484, at Wildhaus, a mountain village of the Toggenburg, the third of the eight sons of the Amtmann of

that place. After a six years' course at the schools of Basel and Bern, he studied philosophy at Vienna, 1499–1501, and theology under Wyttenbach at Basel, 1502–6. He was appointed pastor at Glarus in 1506, and here he devoted himself in his newly-founded Latin school to the education of the young with an ardour that called forth the praises of Erasmus, and drew around him a circle of enthusiastic pupils, one of whom was the patriotic historian Ægidius Tschudi. At the same time he studied the Latin classics and fathers, and in 1513 commenced the study of Greek, writing down the epistles of Paul in the original, and committing them to memory. In 1513, and again in 1515, as army chaplain, he accompanied the Glarus contingent of the army raised in Switzerland to drive the French out of Lombardy, and gave striking evidence of his personal courage on the disastrous field of Marignano (September 14th and 15th, 1515). For his services he received until 1517 a pension from the Pope of fifty crowns, ostensibly granted to assist him in purchasing books to pursue his studies. On his return Z. wrote a strong remonstrance to several of the cantonal governments against the prevailing practice of foreign enlistment. As his knowledge of the Scriptures and the fathers extended, he found himself drifting farther and farther from the received traditions of the Church. In 1516 he was called by Diebold von Geroldseck to be preacher to the monastery of Maria-Einsiedeln, the most frequented place of resort for the pilgrims of S. Germany, Switzerland, and the E. of France, and here he preached with great boldness the inefficacy of pilgrimages and formal devotions, and proclaimed the Scriptures to be the only safe rule in matters of faith. At the same time he implored his bishop, Hugo of Constance, as well as Cardinal Schinner, to aid in reforming discipline and restoring the Church to its ancient purity. In December 1518 he was called to the cathedral at Zürich, by the votes of 17 of the 24 canons. Here, as at Einsiedeln, Z. fiercely opposed Bernhardin Sampson, the vendor of indulgences, and succeeded in preventing his entrance into the town. He now devoted himself to pastoral work with apostolic zeal, and preached the new doctrines with such success that on January 29, 1523, the Great Council of Zürich held a public conference for the free discussion of the points at issue. Here Z.'s unrivalled power of debate enabled him to overthrow his opponents, the ablest of whom was Johann Faber, the vicar-general of Bishop Hugo, and afterwards Bishop of Vienna; and the Great Council came to a resolution that Z. should continue to preach as before, and that the pastors of the town and territory of Zürich should base their discourses on the Scriptures alone. At a second conference, held October 26–29 of the same year, Z. argued before 900 persons against the worship of images and the mass, and the consequence was the removal of all images from the churches of Z. A third conference, on January 13 and 14, 1524, resulted in the abolition of the mass. In the same year Z. married Anna Meyer (*née* Reinhard), a widow of forty-three. He now became almost temporal and spiritual dictator of Zürich, reorganised the whole system of public instruction, brought marriages under the civil courts, and diverted the surplus revenues of the religious houses to founding hospitals and schools; but in no case, unlike almost all other countries, did the secularisation of Church property lead to its being swallowed by the State or embezzled by powerful individuals. New troubles soon arose with the fanatical Anabaptists, and Z. held several conferences with them, without, however, convincing them of the impracticability of their schemes, nor were they silenced until severe measures were resorted to by the Government. Z. was not allowed by the Council of Zürich to attend the conference held at Baden in Aargau in 1526, but he attended the nineteen days' conference which commenced January 6, 1528, at Bern, and as it had been granted that no argument should be used not founded on a text of Scripture, he won a brilliant victory and brought over the canton of Bern to the Reformation. In September 1528 Z. repaired with Æcolampadius to Marburg, to hold a conference with Luther and Melancthon, which had been organised by Philip of Hesse. After three days of eager and sometimes intemperate debate, the conference was broken up, fourteen articles having been agreed upon and signed, but unable to come to an agreement upon the Eucharist, Z. contending that the 'outward symbols of the blood and body of Christ undergo no supernatural change in the Eucharist.' In the year 1531, after much angry controversy, the five cantons of Lüzern, Zug, Schwytz, Uri, and Unterwalden declared war on Bern and Zürich, and invaded the territory of the latter nearly 8000 strong. Zürich, taken at a disadvantage, could only send 2000 men, and Z. was commanded by the Great Council to carry to the field the great banner of the Republic, which had ever been borne in battle by a priest. The Zürichers were terribly defeated in the unequal struggle, and Z. received his death wound on the field of battle while stooping to relieve a wounded soldier at Cappel (q. v.), October 11, 1531. His *Sämmtliche Werke* were published first in folio (Zür. 1545 and 1581; last ed. by Schuler and Schulthess, 8 vols. Zür. 1828–42, supplement, 1861). See Hottinger, *Z. und seine Zeit* (Zür. 1842; Eng. trans. Harrisburg, U.S., 1856); Spörri, *Z. Studien* (Leip. 1866), and the biographies by Christoffel (1857; Eng. trans. Edin. 1858) and Mörikofer (2 vols. Leip. 1867–69).

Zwoll'e, the capital of the Dutch province of Overyssel on the Zwarte ('Black') Water, 25 miles N. of Zütphen by rail, was once a strong fortress with eleven bastions and three forts. It is a handsome, well-built city, with three fine suburbs. Its corn-market is one of the best in Holland. Its chief buildings are St. Michael's Church, a large and splendid building with a famous organ, the government buildings with the provincial archives, the town-hall, and the courts of justice. The town has a Latin school, a school of navigation, an industrial school, a public library with rare works on geography and local history, a museum of natural history, a theatre, &c. Z. has communication with the sea by means of the Willemsvaart Canal. It manufactures oil, spirits, iron goods, and linen, carries on shipbuilding, and a trade in corn and cattle. In a monastery in the neighbourhood Thomas à Kempis lived and died. Pop. (1878) 21,886. Z. was a member of the Hanseatic League.

Zygodac'tyla, a term in zoology denoting the *Suidæ* or Swine, in which the foot is formed of two toes of equal size and of two other toes which do not reach the ground. The term is also applied to those birds (*e.g.*, Scansores, parrots, woodpeckers, &c.) in which the toes are placed two in front and two behind.

Zygophylla'ceæ is a natural order of polypetalous dicotyledons consisting of 17 genera and upwards of 100 species of shrubs or herbs with more or less jointed stems, flowers on axillary peduncles, and generally white, red, or yellow, sepals and petals mostly five, and a dry fruit often separating into cocci. The species are widely dispersed over the tropical and sub-tropical zones, a few also occurring in temperate climates. In the type genus, *Zygophyllum*, the leaves are opposite and consist of two leaflets (Gr. *zugon*, 'a yoke,' and *phyllon*, 'a leaf'). *Z. fabago* has vermifuge properties and its flower buds serve as a substitute for capers. *Z. coccineum* has aromatic seeds employed by the Arabs in place of pepper. The wood called *lignum vitæ* is the most important product of the order. See GUAIACUM.

Zylog'raphy, or **Xylog'raphy**. A new process of printing designs on wood which is applicable to the decoration of panelling, skirtings, mantel-shelves, furniture, &c. Invented by Mr. T. Whitburn and perfected by Mr. Maurice Young, this process is the basis of a new British art manufacture which has been established at Godalming, Surrey. The *modus operandi* is as follows:—An arabesque or floral design is drawn and engraved on a wood block, and from it an electrotype is taken, which is employed to print on thin slabs of soft pine wood. The electrotype is coated with ink, and placed face downwards on the wood to be printed, and a regulated pressure is then applied in an ordinary hand-press. Highly artistic results are thus obtained at a trifling cost. The inks are dark brown and black in colour, and are specially prepared for the process.

Zymot'ic Disea'ses (from Gr. *zymē*, 'a ferment') are, according to Dr. Farr's classification, diseases that are either epidemic, endemic, communicable, inoculable, capable of propagation from existing foci, or of generation; induced by a specific material, which may be named a *poison*, or by want of food, or by its bad quality. Z. D. are arranged into four orders, viz., Miasmatic, Enthetic, Dietic, and Parasitic.

The *Miasmatic* order includes the following diseases, viz., small-pox, measles, scarlatina, diphtheria, quinsy, croup, hooping-cough, typhus, enteric, relapsing, and simple continued fever, erysipelas, puerperal fever, carbuncle, influenza, dysentery, diarrhœa, cholera, ague, remittent fever, rheumatism, &c. The *Enthetic* order comprehends syphilis, hydrophobia, glanders, &c. The *Dietic* order includes privation, purpura, and scurvy, alco-

halism, &c. The *Parasitic* order comprises such diseases as thrush, worms, &c.

By far the most important of the Z. D. are the *acute infectious diseases*, such as small-pox, enteric fever, relapsing fever, typhus fever, cholera, plague, yellow fever, dysentery, diphtheria, measles, scarlatina, hooping-cough, erysipelas, puerperal fever, cerebro-spinal fever, &c. When more precise knowledge regarding the intimate pathology of these diseases has been acquired, it is probable that they will admit, like different species of plants and animals, of a more or less strict philosophical classification; but they all possess, in common, certain well-marked characteristics. They originate through the infection of the system with certain poisonous matters, which are mainly distinguished as ordinary poisons by the fact that they can reproduce themselves under favouring conditions to an endless degree. They are endemic when they are limited to a certain territorial district, and epidemic when they appear at intervals and then again disappear; but each endemic or epidemic disease is not necessarily infectious. The mortality from infectious diseases forms a very large portion of the total mortality. The term zymotic disease applied to the infectious diseases is derived from a theory regarding the origin and mode of propagation of such diseases; for among chemical actions it is chiefly the processes of fermentation and decomposition, which by their capacity for extension, by means of which the smallest possible quantity of matter show the most striking analogy to the contagious diseases. The hypothesis, however, of a *contagium vivum* is consistent with those ferment processes, for both are associated with the presence and multiplication of low organisms; and the existence of disease poisons which have the property of indefinite multiplication necessarily gives rise to the theory of a *contagium vivum*. In the great majority of infectious diseases, the existence of organised disease poisons has not been demonstrated by actual observation; but several diseases which were formerly regarded as simply infectious are now classed among the *parasitic* diseases owing to the demonstration of low organisms sufficient to account for the phenomena of the diseases. One marked peculiarity of the infectious diseases, which they have in common with the poisons proper, is their specificness, so that always and under all circumstances a given disease is solely due to a given kind of morbid agent or cause; or, in other words, each disease breeds true. In diseases of this class the predisposing cause is to be considered only in so far as there may be a question of special susceptibility, and in so far as it may determine the severity of the disease; but the disease itself is entirely independent of it. No individual or external influence decides the nature of the affection, and one infectious disease is never changed into another. From the specificness of infectious diseases it is inferred that there is a continued propagation of the disease poison, and that they never originate spontaneously or *de novo*; but this conclusion is not generally accepted. Another peculiarity belonging to many but not to all infectious diseases, consists in the fact that a single attack of the disease successfully surmounted confers an absolute or relative immunity from it for a certain time, or even for the remainder of life; and it is probable that during the disease there is a destruction or change in the body of some of its constituents necessary for the development of the disease poison.

The important facts in connection with the entire class of Z. D. are that they depend upon causes external to the human frame; that these causes are distinctly preventible; and that the recent advances in sanitary science are sufficient to enable the community to aim, with a reasonable hope of success, at the total extermination of Z. D.

THE END.
